

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

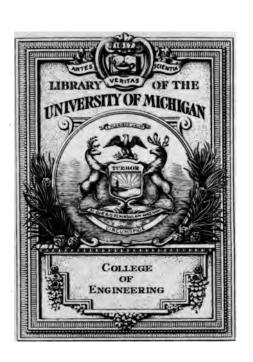

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + Refrain from automated querying Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

PREFACE

This Handbook of Mathematics is designed to contain, in compact form, accurate statements of those facts and formulas of pure mathematics which are most likely to be useful to the worker in applied mathematics.

It is not intended to take the place of the larger compendiums of pure mathematics on the one hand, or of the technical handbooks of engineering on the other hand; but in its own field it is thought to be more comprehensive than any other similar work in English.

Many topics of an elementary character are presented in a form which permits of immediate utilization even by readers who have had no previous acquaintance with the subject; for example, the practical use of logarithms and logarithmic cross-section paper, and the elementary parts of the modern method of nomography (alignment charts), can be learned from this book without the necessity of consulting separate treatises.

Other sections of the book to which special attention may be called are the chapter on the algebra of complex (or imaginary) quantities, the treatment of the catenary (with special tables), and the brief résumé of the theory of vector analysis.

The mathematical tables (including several which are not ordinarily found) are carried to four significant figures throughout, and no pains have been spared to make them as nearly self-explanatory as possible, even to the reader who makes only occasional use of such tables.

For the Tables of Weights and Measures, which add greatly to its usefulness, the book is indebted to Mr. Louis A. Fischer of the U. S. Bureau of Standards.

All the matter included in the present volume was originally prepared for the Mechanical Engineers' Handbook (Lionel S. Marks, Editor-in-Chief), and was first printed in 1916, as Sections 1 and 2 of that Handbook. The author desires to express his indebtedness to Professor Marks, not only for indispensable advice as to the choice of the topics which would be most useful to engineers, but also for great assistance in many details of the presentation.

All the misprints that have been detected have been corrected in the plates. Notification in regard to any further corrections, and any suggestions toward the improvement or possible enlargement of the book, will be cordially welcomed by the author or the publishers.

Explanation of Table of Squares (pp. 2-7).

This table gives the value of N^3 for values of N from 1 to 10, correct to four figures. (Interpolated values may be in error by 1 in the fourth figure).

To find the square of a number N outside the range from 1 to 10, note that

To find the square of a number N outside the range from 1 to 10, note that moving the decimal point one place in column N is equivalent to moving it two places in the body of the table. For example:

 $(3.217)^2 = 10.35$; $(0.03217)^2 = 0.001035$; $(3217)^2 = 10350000$ This table can also be used inversely, to give square roots.

SQUARES (continued)

Explanation of Table of Cubes (pp. 8-11).

This table gives the value of N^3 for values of N from 1 to 10, correct to four figures. (Interpolated values may be in error by 1 in the fourth figure.)

To find the cube of a number N outside the range from 1 to 10, note that

moving the decimal point one place in column N is equivalent to moving it three places in the body of the table. For example: $(4.852)^2 = 114.2$; $(0.4852)^2 = 0.1142$; $(485.2)^2 = 114200000$ This table may also be used inversely, to give cube roots.

CUBES	(continued)

Explanation of Table of Square Roots (pp. 12-15).

This table gives the values of \sqrt{N} for values of N from 1 to 100, correct to four figures. (Interpolated values may be in error by 1 in the fourth figure.)

To find the square root of a number N outside the range from 1 to 100, divide the digits of the number into blocks of two (beginning with the decimal point), and note that moving the decimal point two places in N is equivalent to moving it one place in the square root of N. For example:

$$\sqrt{2.718}$$
 = 1.648; $\sqrt{271.8}$ = 16.48; $\sqrt{0.0002718}$ = 0.01648; $\sqrt{27.18}$ = 5.213; $\sqrt{2718}$ = 52.13; $\sqrt{0.002718}$ = 0.05213.

Explanation of Table of Cube Roots (pp. 16-21).

This table gives the values of $\sqrt[3]{N}$ for all values of N from 1 to 1000, correct to four figures. (Interpolated values may be in error by 1 in the fourth figure.)

To find the cube root of a number N outside the range from 1 to 1000, divide the digits of the number into blocks of three (beginning with the decimal point), and note that moving the decimal point three places in column N is equivalent to moving it one place in the cube root of N. For example:

```
\sqrt[3]{2.718} = 1.396; \sqrt[3]{2718} = 13.96; \sqrt[3]{0.00002718} = 0.01396.
\sqrt[3]{27.18} = 3.007; \sqrt[3]{27180} = 30.07; \sqrt[3]{0.0002718} = 0.03007.
\sqrt[3]{271.8} = 6.477; \sqrt[3]{271800} = 64.77; \sqrt[3]{0.0002718} = 0.06477.
```

This table gives $N^{\frac{3}{2}}$ from N=1 to N=100. Moving the decimal point TWO places in N requires moving it THREE places in body of table. Thus: $(7.23)^{\frac{3}{2}} = 19.44; \qquad (723)^{\frac{3}{2}} = 19440; \qquad (0.0723)^{\frac{3}{2}} = 0.01944$ $(72.3)^{\frac{3}{2}} = 614.8; \qquad (7230)^{\frac{3}{2}} = 614800; \qquad (0.723)^{\frac{3}{2}} = 0.6148$ Used inversely, table gives $M^{\frac{3}{2}}$ from M=1 to M=1000. Thus: $(0.6148)^{\frac{3}{2}} = 0.7230$.

Explanation of Table of Reciprocals (pp. 24-27).

This table gives the values of 1/N for values of N from 1 to 10, correct to four figures. (Interpolated values may be in error by 1 in the fourth figure.)

To find the reciprocal of a number N outside the range from 1 to 10, note that moving the decimal point any number of places in either direction in column N is equivalent to moving it the same number of places in the opposite direction in the body of the table. For example:

$$\frac{1}{3.217} = 0.3108$$
; $\frac{1}{3217} = 0.0003108$; $\frac{1}{0.003217} = 310.8$

Explanation of Table of Circumferences (pp. 28-29)

Circumference = $\pi \times \text{diam.} = 3.141593 \times \text{diam.}$

Conversely,

Diameter = $\frac{1}{\tau}$ × circumf. = 0.31831 × circumf.

This table gives the product of π times any number D from 1 to 10; that is, it is a table of multiples of π . (D = diameter.)

Moving the decimal point one place in column D is equivalent to moving it one place in the body of the table.

MATHEMATICAL TABLES

CIRCUMFERENCES BY HUNDREDTHS (continued)

Explanation of Table of Areas of Circles (pp. 30-31)

Moving the decimal point one place in column D is equivalent to moving it two places in the body of the table. (D = diameter.)

Area of circle = $\frac{\pi}{4}$ × (diam.2) = 0.785398 × (diam.2)

Conversely,

Diam. =
$$\sqrt{\frac{4}{\pi}} \times \sqrt{\text{area}} = 1.128379 \times \sqrt{\text{area}}$$

If given diameter is not found in this table, reduce diameter to feet and decimals of a foot by aid of the following auxiliary table, and then find area from pp. 30-31.

Fro	m Inch	es and	l Frac	tions	of an	Inch t	o Dec	imals	of a F	oot	
Inches Feet	.0833	.1667	.2500	.3333	.4167	, 5000	. 5833	. 6667	.7500	. 8333	.9167
Inches Feet Example.	3/8 .0104 5 ft. 73					.0625 .0313		146 ft.			

SEGMENTS OF CIRCLES, GIVEN h/c

Given: h = height; c = chord. (For explanation of this table, see p. 38)

h c	Diam.	Diff.	Aro	Diff.	$\frac{\text{Area}}{h \times c}$	Diff.	Central angle, s	Diff.	Diam.	Diff.

Explanation of Table of Volumes of Spheres (pp. 36-37)

Moving the decimal point one place in column D is equivalent to moving it three places in the body of the table. (D = diameter.)

Volume of sphere =
$$\frac{\pi}{6}$$
 × (diam.*) = 0.523599 × (diam.*)

Conversely,

Diam. =
$$\sqrt[8]{\frac{3}{\sqrt{2}}} \sim \sqrt[3]{\text{volume}} = 1.240701 \times \sqrt[3]{\text{volume}}$$

 $\log \pi = 0.4971$ $\log s = 0.4343$ $\log \pi/2 = 0.1961$ $\log \pi^2 = 0.9943$ $\log (0.4343) = 0.6378 - 1$ $\log \sqrt{\pi} = 0.2486$

These two pages give the common logarithms of numbers between 1 and 10, correct to four places. Moving the decimal point n places to the right [or left] in the number is equivalent to adding n [or -n] to the logarithm. Thus, $\log 0.017453 = 0.2419 - 2$, which may also be written $\overline{2}.2419$ or 8.2419 - 10. See p. 91. Graphs, p. 174. $\log (a^N) = N \log a$

$$\log (ab) = \log a + \log b \qquad \log (a^N) = N \log a$$

$$\log \left(\frac{a}{b}\right) = \log a - \log b \qquad \log \left(\frac{N}{\sqrt{a}}\right) = \frac{1}{N} \log a$$

^{1/(0.4343) = 2.3026}

For table of multiples of 0.4343, see p. 62. Graphs, p. 174.

HYPERBOLIC LOGARITHMS

	n	n (2.3026)	n (0.6974-3)
These two pages give the natural (hyperbolic, or Napierian) logarithms (loga) of numbers between 1 and 10, correct to four places. Moving the decimal point n places to the right [or left] in the number is equivalent to adding n times 2.3026 [or n times 3.6974] to the logarithm. Base $e=2.71828+$	1 2 3 4 5 6 7 8 9	2.3026 4.6052 6.9078 9.2103 11.5129 13.8155 16.1181 18.4207 20.7233	0.6974-3 0.3948-5 0.0922-7 0.7897-10 0.4871-12 0.1845-14 0.8819-17 0.5793-19 0.2767-21

COMPOUND INTEREST. AMOUNT OF A GIVEN PRINCIPAL

The amount A at the end of n years of a given principal P placed at compound interest to-day is $A = P \times x$ or $A = P \times y$ or $A = P \times z$, according as the interest (at the rate of r per cent. per annum) is compounded annually, semi-annually, or quarterly; the factor x or y or z being taken from the following tables.

Values of x. (Interest compounded annually; $A = P \times x$.) AMOUNT OF AN ANNUITY

The amount S accumulated at the end of n years by a given annual payment Y set aside at the end of each year is $S = Y \times v$, where the factor v is to be taken from the following table. (Interest at r per cent. per annum, compounded annually.)

Values of v r = 221/2 3 31/2 4 41/2 5 6 7 Years 1.0000 1.0000 1.0000 1.0000 1.0000 1.0000 1.0000 1.0000 1.0000 2.0450 3.1370 2.0250 3.0756 2.0300 2.0350 2.0400 2.0500 3.1525 2 2.0200 2.0600 2.0700 3.0604 3.0909 3.1062 3.1216 3.1836 3.2149 (⁷/100) 4.1525 4 4.1836 4.2149 4.2782 4.3101 4.3746 4.4399 4.1216 4.2465 5 6 7 5.2040 5.2563 5.3091 5.3625 5.4163 5.4707 5.5256 5.6371 5.7507 6.3081 7.4343 8.5830 6.3877 7.5474 8.7361 9.9545 6.4684 7.6625 6.5502 7.7794 6.6330 6.7169 6.8019 6.9753 7.1533 + 7.8983 9.2142 8.1420 9.5491 8.3938 8.0192 8.6540 = 9.0517 9.3800 89 8.8923 9.8975 10.260 10.368 9.7546 10.159 10.583 10.802 11.027 11.491 11.978 ı 10 10.950 12.169 11.203 11.464 12.808 11.731 12.006 12.288 12,578 13.816 13.181 (r/100) (r/100)]* 14.207 15.917 17.713 12.483 13.796 15.140 13.841 15.464 14.972 13.142 13.486 15.784 12 13 13.412 14.192 15.026 14.602 16.870 17.888 14.680 15.974 15.618 17.086 16.113 16.627 17.160 18.882 20.141 + 18.932 14 16.519 17.677 18.292 19.599 21.015 17.932 19.296 20.784 21.579 17.293 18.599 20.024 23.276 25,129 15 + ١ 16 17 18 19,380 20.971 23.657 25.673 18.639 20.157 21.825 22,719 27.888 ⊒ કું 20.865 22.386 24.742 26.855 25.840 28.132 30.840 33.999 20.012 21.762 22.705 23.698 28.213 24.500 23.414 25.645 30.906 21.412 . 26.357 19 22.841 23.946 25.117 27.671 29.064 30.539 33.760 **37.379** 8 20 25 30 25.545 24.297 26.870 28,280 29.778 31.371 33.066 36.786 40.995 32.030 34.158 38.950 41.646 44.565 54.865 Formula 36.459 47.727 63.249 40.568 43.903 47.575 51.623 56.085 61.007 66,439 79.058 94.461 67.403 97.484 120.80 154.76 290.34 199.64 40 60.402 75.401 84.550 95.026 107.03 50 60 84.579 114.05 112.80 131.00 152.67 237.99 178.50 209.35 406.53 135.99 196.52 289.50 163.05 353.58 533.13 813.52

PRINCIPAL WHICH WILL AMOUNT TO A GIVEN SUM

The principal P, which, if placed at compound interest to-day, will amount to a given sum A at the end of n years is $P = A \times x'$ or $P = A \times y'$ or $P = A \times z'$, according as the interest (at the rate of r per cent. per annum) is compounded annually, semi-annually, or quarterly; the factor x' or y' or z' being taken from the following tables.

Values of x'. (Interest compounded annually; $P = A \times x'$)

PRESENT WORTH OF AN ANNUITY

The capital C, which, if placed at interest to-day, will provide for a given annual payment Y for a term of n years before it is exhausted is $C = Y \times w$, where the factor w is given below. (Interest at r per cent. per annual, compounded annually.) Values of w

ANNUITY PROVIDED FOR BY A GIVEN CAPITAL

The annual payment Y provided for for a term of n years by a given capital C placed at interest to-day is $Y = C \times w'$. (Interest at r per cent. per annum, compounded annually; the fund supposed to be exhausted at the end of the term.)

WEIGHTS AND MEASURES

BY

LOUIS A. FISCHER

In the United States the measures of weight and length commonly employed are identical with the corresponding English units, but the capacity measures differ from those now in use in the British Empire, the U. S. gallon being defined as 231 cu. in. and the bushel as 2150.42 cu. in., whereas the corresponding British imperial units are, respectively, 277.418 cu. in., and 2219.344 cu. in. (1 imp. gal. = 1.2 U. S. gal., approx.; 1 imp. bu. = 1.03 U. S. bu., approx.).

The metric system of weights and measures was legalized and its use made permissive in the United States by an Act of Congress, passed in 1866. In 1872, by the concurrent action of the principal governments of the world, it was agreed to establish an International Bureau of Weights and Measures

near Paris.

Prior to 1891 the British imperial yard was regarded as the real standard of the United States. In 1891, the Office of Weights and Measures (now Bureau of Standards) fixed the value of the United States yard in terms of the international meter, according to the ratio: one yard = 3600/3937 meters. At the same time, the pound was fixed in terms of the international kilogram, according to the relation: one pound = 453.59243 grams.

U. S. Customary Weights and Measures

Measure	s of Length	Measures of Area

7.92 inches 100 links = 66 ft. = 60 chains 33½ inches		1728 cubic inches = 1 cubic foot 27 cubic feet = 1 cubic yard 1 cord of wood = 128 cu. ft. 1 perch of masonry = 16½ to 25 cu. ft.					

U. S. Customary Weights and Measures—(continued)

Measures of Volume	Weights (The grain is the same in all systems)				
Liquid or Fluid Measure 4 gills1 pint 2 pints -1 quart 4 quarts -1 gallon 7.4805 gallons -1 cubic foot (There is no standard liquid "barrel.")	Avoirdupois Weight 16 drams = 437.5 grains = 1 ounce 16 ounces = 7000 grains = 1 pound 100 pounds = 1 cental 2000 pounds = 1 short ton 2240 pounds = 1 long ton				
Apothecaries' Liquid Measure 60 minims = 1 liquid dram or drachm 8 drams = 1 liquid ounce 16 ounces = 1 pint Water Measure	Also (in Great Britain): 14 pounds				
The Miner's Inch is the quantity of water that will pass through an orifice 1 sq. in. in cross-section under a head of from 4 to 6½ in., as fixed by statutes, and varies from ½0 cu. ft. to ½0 cu. ft. per sec. The units now most in use are 1 cu. ft. per sec. and 1 gal. per sec., the U. S. Reclamation Service employing the former. See p. 260. Dry Measure 2 pints = 1 quart 8 quarts = 1 peck 4 pecks = 1 bushel Shipping Measure 1 Register ton = 100 cu. ft. 1 U. S. shipping ton = 40 cu. ft.	_				
= { 32.14 U. S. bu. 31.14 imp. bu. 1 British shipping ton = 42 cu. ft. = { 32.70 imp. bu. 33.75 U. S. bu.	20 grains = 1 scruple 3 3 scruples = 60 grains = 1 dram 3 8 drams = 1 ounce 3 12 ounces = 5760 grains = 1 pound Weight for Precious Stones				
Board Measure { 144 cu. in. = volume of } board foot = { board 1 ft. sq. and 1 in. } thick.	1 carat = 200 milligrams (Adopted by practically all important nations.)				
No. of board feet in a $\log = [\frac{1}{2}((d-4))^2L]$, where $d=\dim$ of \log (usually taken inside the bark at small end), in., and $L=$ length of \log , it. The 4 in. deducted are an allowance for slab. This rule is variously known as the Doyle, Conn. River, St. Croix, Thurber, Moore and Beeman,	Gircular Measure 60 seconds = 1 minute 60 minutes = 1 degree 90 degrees = 1 quadrant 360 degrees = circumference 57.2957795 degrees = 1 radian (or angle (=57° 17'44.806") having arc of length				

METRIC SYSTEM

equal to radius)

and the Scribner rule.

The fundamental unit of the metric system is the **meter**—the unit of length, from which the units of volume (liter) and of mass (gram) are derived. All other units are the decimal subdivisions or multiples of these. These three units are simply related: one cubic decimeter equals one liter, and one liter of water weighs one kilogram. The metric tables are formed by combining the words "meter," "gram," and "liter" with numerical prefixes.

ŧ

All lengths, areas, and cubic measures in the following conversion tables are derived from the international meter. The customary weights are likewise derived from the kilogram. All capacities are based on the practical equivalent: 1 cubic decimeter equals 1 liter. (The liter is defined as the volume occupied by the mass of 1 kilogram of water under a pressure of 76 cm. of mercury and at the temperature of 4 deg. cent. According to the best information, 1 liter = 1.000027 cubic decimeters.)

The customary weights derived from the international kilogram are based on the value 1 avoirdupois lb. = 453.59243 grams. The value of the troy lb. is based on the same relation and also the equivalent 5760/7000 avoirdupois lb. equals 1 troy lb.

SYSTEMS OF UNITS

The principal units of interest to mechanical engineers can all be derived from the three fundamental units of force, length, and time. These three fundamental units may be chosen at pleasure; each such choice gives rise to a "system" of units. The following table gives the units of the four "systems" most often met with in the literature.

UNITS 73

The precise definitions of the fundamental units in these systems are as follows. (In these definitions the "standard pound body" and the "standard kilogram body" refer to two special lumps of metal, carefully preserved at London and Paris, respectively; the "standard locality" means sea level, 45 deg. latitude; or, more strictly, any locality in which the acceleration due to gravity has the value 980.665 cm. per sec.2 = 32.1740 ft. per sec.2, which may be called the standard acceleration.

The pound (force) is the force required to support the standard pound body against gravity, in vacuo, in the standard locality; or, it is the force which, if applied to the standard pound body, supposed free to move, would give that body the "standard acceleration." The word "pound" is used for the unit of both force and mass, and consequently is ambiguous. To avoid uncertainty it is desirable to call the units

pound force" and "pound mass," respectively.

The kilogram (force) is the force required to support the standard kilogram against gravity, in vacuo, in the standard locality; or, it is the force which, if applied to the standard kilogram body, supposed free to move, would give that body the "standard accelera-tion." The word "kilogram" is used for the unit of both force and mass and consequently is ambiguous. To avoid uncertainty it is desirable to call the units "kilogram force" and "kilogram mass," respectively.

The poundal is the force which, if applied to the standard pound body, would give that body an acceleration of 1 ft. per sec.2; that is, 1 poundal = 1/32.1740 of a pound

The dyne is the force which, if applied to the standard gram body, would give that body an acceleration of 1 cm. per sec.2; that is, 1 dyne = 1/980.665 of a gram force.

Systems of Units

		23 200 2	01 011100		
Name of unit	Dimensions of units in terms of F, L, T British "gravitational" system, or tem, or foot-pound-second" system		Metric "gravita- tional" sys- tem, or "kilogram- meter-sec- ond" system	Metric "absolute" system, or "C. G. S." system	British "absolute" system (little used)
Force Length Time	F L T	1 lb. 1 ft. 1 sec.	1 kg. 1 m. 1 sec.	1 dyne 1 cm. 1 sec.	1 poundal 1 ft. 1 sec.
Velocity Acceleration Pressure Impulse or	L/T L/T^2 F/L^2	1 ft. per sec. 1 ft. per sec. ² 1 lb. per ft. ²	1 m. per sec. 1 m. per sec. ² 1 kg. per m. ²	1 cm. per sec. 1 cm. per sec. ² 1 dyne per cm. ²	1 ft. per sec. 1 ft. per sec. ² 1 pdl. per ft. ²
momentum Work or	FT	1 lbsec.	1 kgsec.	1 dyne-sec.	1 pdlsec.
energy	FL	1 ftlb.	1 kgm.	1 dyne-cm. = 1 "erg."	1 ftpdl.
Power	FL/T	1 ftlb. per sec.	1 kgm. per	1 dyne-cm. per sec.	1 ftpdl. per sec.
Mass	$F/(L/T^2)$	1 lb. per (ft. per sec.²) = 1 "slug."	1 kg. per (m. per sec.²) = 1 "metric slug."	1 dyne per (cm. per sec.²) = 1 gram mass.	1 pdl. per (ft. per sec.²) = 1 pound mass.

NOTE. The "slug" (also called the "geepound," or the "engineer's unit of mass"), the "metric slug," and the "poundal" are never used in practice.

Other common units are as follows:

1 joule = 10^7 ergs = 10,000,000 dyne-cm. Work:

1 kilowatt-hour = 3,600,000 joules = 3600×10^{10} dyne-cm.

Power: 1 horse power = 550 ft.-lb. per sec.

1 poncelet = 100 kg.-m. per sec.

1 force de cheval = 75 kg.-m. per sec.

1 watt = 1 joule per sec. = 10,000,000 dyne-cm. per sec.

1 kilowatt = 1000 watts = 1010 dyne-cm. per sec.

A new horse power of 550.220 ft.-lb. per sec., or 746 watts, has been proposed, but has not been accepted by mechanical engineers.

The weight of a body (in a given locality) always means a force, namely, the force, re-

quired to support the body against gravity (in that locality). When no particular locality is specified, the standard locality may be assumed. Thus, the "standard weight" of the pound body is 1 lb.; the "standard weight" of the kilogram body is 1 kg.

Heat Units. The units of heat commonly used are (1) the quantity of heat required to raise the temperature of 1 gram of water 1 deg. cent. at a mean temperature of 15 deg. cent., or (2) the heat required to raise the temperature of 1 lb. of water 1 deg. fahr. The former quantity is called the gram-calorie (small calorie), while the latter is known as the British thermal unitor B.t.u.

Force Equivalents

Dynes X 10 ⁶	Kilograms	Pounds	Poundals
1	1.020	2,248	72.33
	0.00848	0.03518	1.85933

"See Marks' MECHANICAL ENGINEERS' HANDBOOK.

Mechanical Equivalent of Heat. See p. 311.* The value most commonly accepted among American engineers as the work equivalent of 1 mean B.t.u. is 777.5 ft.-lb., and the mean gram-calorie = 4.183 joules, which are the values used throughout this book. The U. S. Bureau of Standards does not recommend any special value; for its own purposes it takes the 59 deg. fahr. B.t.u. as 778.2 ft.-lb. and the 68 deg. B.t.u. as 777.5 ft.-lb. The 15 deg. calorie = 4.187 joules; 20 deg. calorie = 4.183 joules. There is an uncertainty of about 1 part in 1000 in these values.

TIME 83

TIME

Three kinds of time are recognized by astronomers, viz., Kinds of Time. sidereal, apparent solar, and mean solar time. The sidereal day is the interval between two consecutive transits of some fixed celestial object across any given meridian, or it is the interval required by the earth to make one complete revolution on its axis. This interval is constant but it is inconvenient as a time unit because the noon of the sidereal day occurs at all hours of the day and night. The apparent solar day is the interval between two consecutive transits of the sun across any given meridian. On account of the variable distance between the sun and earth, the variable speed of the earth in its orbit, the effect of the moon, etc., this interval is not constant and consequently cannot be kept by any simple mechanism, such as clocks or watches. To overcome the objection noted above, the mean solar day was devised. The mean solar day is the length of the average apparent solar day. Like the sidereal day it is constant, and like the apparent solar day its noon always occurs at approximately the same time of day. The astronomical day begins at mean solar noon and the hours run from one to twenty-four, while the civil day (mean solar) begins 12 hours earlier, at midnight, and the hours run from one to twelve, and then repeat from noon to midnight.

The Year. There are three different kinds of year used, the sidereal, the tropical, and the anomalistic. The sidereal year is the time taken by the earth to complete one revolution around the sun from a given star to the same star again. Its length is 365 days, 6 hours, 9 minutes, and 9 seconds. The tropical year is the time included between two successive passages of the vernal equinox by the sun, and since the equinox moves westward 50."2 of arc a year, the tropical year is shorter by 20'23."5 in time than the sidereal year. As the seasons depend upon the earth's position with respect to the equinox, the tropical year is the year of civil reckoning. The anomalistic year is the interval between two successive passages of the perihelion, namely, the time of the earth's nearest approach to the sun. The anomalistic year is only used in special calculations in astronomy.

The Calendar. The month depended originally upon the changes of the moon. The Mohammedan nations still use a lunar calendar with years of twelve lunar months, which alternately contain 355 and 356 days. According to their method of reckoning the same month falls in different seasons, and their calendars gain 1 year on ours every 33 years. The Julian Calendar (established 45 B. C.) discards all consideration of the moon and adopts 365¼ days as the true length of the year. It is still used in Russia and generally by the Greek Church. Gregorian Calendar: The true length of the tropical year is 365 days, 5 hr., 48 min., 45.5 sec., a difference of 11 min., 14.5 sec. by which the Julian year is too long. This amounts to a little more than 3 days in 400 years. To correct for this, those century years are made leap years which are divisible by 400 without remainder.

Standard Time. Prior to 1883 each city of the U. S. had its own time, which was determined by the time of passage of the sun across the local meridian. A system of standard time is used at present, according to which the United States, which extends from 65 deg. to 125 deg. West longitude, is divided into four sections, each of 15 deg. of longitude. The first or eastern section includes all territory between the Atlantic coast and an irregular line drawn from Detroit, Mich., through Pittsburg to Charleston, S. C., its most southern point. The time of this section is that of the 75-deg. meridian, which is 5

hr. slower than Greenwich time. The second (central) section includes all territory between the line mentioned, and an irregular line drawn from Bismarck, N. D., to the mouth of the Rio Grande. The third (mountain) section includes all territory between the last-named line and a line which passes through the western part of Idaho, Utah and Arizona. The fourth (Pacific) section covers the rest of the country to the Pacific Ocean. Standard time is uniform in each of these sections, but the time in one section differs by exactly 1 hr. from the section next to it. In cities situated on the border line of two sections, as, say, Pittsburg and Atlanta, the standard times of both sections are used, and in such cities when the time is given, it should be specified as eastern, central, etc. The system of standard time has been adopted in almost all civilized countries. All continental Europe, except Russia, uses a time 1 hr. faster than that of Greenwich; in Japan and Australia the time is 9 hr. faster.

TERRESTRIAL GRAVITY

By standard gravity is meant any locality where $g_0 = 980.665$ cm. per sec. per sec., or 32.1740 ft. per sec. per sec. This value, g_0 , is assumed to be the value of g at sea level and latitude 45 deg.

Correction for altitude above sea level: - 0.3 cm. per sec.² for each 1000 meters; - 0.003 ft. per sec.² for each 1000 feet.

SPECIFIC GRAVITY AND DENSITY

The specific gravity of a solid or liquid is the ratio of the mass of the body to the mass of an equal volume of water at some standard temperature. At the present time a temperature of 4 deg. cent. (39 deg. fahr.) is commonly used by physicists, but the engineer uses 60 deg. fahr. The specific gravity of gases is usually expressed in terms of hydrogen or air.

The density of a body is its mass per unit volume. If the gram is used as the unit of mass and the milliliter as the unit of volume, the figures representing the density are the same as the specific gravity of the body referred to water at 4 deg. cent. as unity. The customary unit is pounds per cu. ft.

The specific gravity of liquids is usually measured by means of an hydrometer (see p. 254).* Special arbitrary hydrometer scales are used in various trades and industries. The most common of these are the Baumé, Twaddell and Beck. Twaddell's hydrometer is used for liquids heavier than water. The number of degrees, N, which it indicates may be converted to specific gravities, G, by the formula G=(5N+1000)/1000. The formula for the Beck hydrometer is $G=170/(170\pm N)$; for the Brix hydrometer $G=400/(400\pm N)$. In both of these the + sign is to be used for liquids lighter than water, the - sign for heavier liquids. For the salinometer (salometer), see p. 1734.* The specific gravities corresponding to the indications of the Baumé hydrometer are given in the following tables.

*See Marks' MECHANICAL ENGINEERS' HANDBOOK.

Specific Gravities at $\frac{60^{\circ}}{60^{\circ}}$ Fahr. Corresponding to Degrees Baumé for Liquids Lighter than Water

for Liquids Lighter than Water

NUMERICAL COMPUTATION

Number of Significant Figures. In any engineering computation, the data are ordinarily the results of measurement, and are correct only to a limited number of significant figures. Each of the numbers 3.840 and 0.003840 is said to be given "correct to four figures;" the true value lies in the first case between 3.8395 and 3.8405; in the second case, between 0.0038395 and 0.0038405. The absolute error is less than 0.001 in the first case, and less than 0.000001 in the second; but the relative error is the same in both cases, namely, an error of less than "one part in 3840.".

If a number is written as 384000, the reader is left in doubt whether the number of correct significant figures is 3, 4, 5, or 6. This doubt can be removed by writing the number as 3.84×10^5 or 3.840×10^5 or 3.8400×10^5 or 3.84000×10^5 .

In any numerical computation, the possible or desirable degree of accuracy should be decided on and the computation should then be so arranged that the required number of significant figures, and no more, is secured. Carrying out the work to a larger number of places than is justified by the data, is to be avoided. (1) because the form of the results leads to an erroneous impression of their accuracy, and (2) because time and labor are wasted in superfluous computation. The labor of working with six-place tables is nearly three times as great as that with four-place tables. In computations involving several steps, it is desirable to retain one extra figure until just before the final result is reached, in order to protect the last figure against the possible cumulative effect of small tabular errors. In discarding superfluous figures, if the first discarded figure is 5 or more, increase the preceding figure by 1. Thus, 3.14159, written correct to four figures, is 3.142; correct to three figures, 3.14. Again, 6.1297, correct to four figures, is 6.130.

Addition. In adding numbers, note that a doubtful final	0.2056x
figure in any one number will render doubtful the whole col-	2.572xx
umn in which that figure lies; hence all figures to the right of	14.25xxx
that column are superfluous, and contribute nothing to the	576.1xxx
accuracy of the result.	

593.1 Subtraction. The "Austrian" or "shop" method is recommended. The mental process is as follows, the figures here printed in boldface type being the only ones written down:

[3 plus how many is 12?] 3 plus 9 is 12; 1 to carry.	14752
[7 plus how many is 15?] 7 plus 8 is 15; 1 to carry.	8463
5 plus 2 is 7. 8 plus 6 is 14.	6289

This method is especially useful when it is desired to subtract from a given number the sum of several other numbers.

7 plus 1 is 8; plus 5 is 13; plus 9 is 22; 2 to carry.	14752
5 plus 0 is 5; plus 2 is 7; plus 8 is 15; 1 to carry.	31257
3 plus 1 is 4; plus 1 is 5; plus 2 is 7.	101
5 plus 3 is 8; plus 6 is 14.	5237
	6289

The use of a wavy line to indicate subtraction is also recommended, as it will minimize the danger of adding when subtraction is intended.

Multiplication. In long examples in multiplication, the arrangement of work here illustrated is recommended, since it facilitates the abbreviation of the work by the omission, in practice, of all the figures on the right of the vertical line.

The **position of the decimal point** should be determined by reference to the first, or left-hand, figures of the numbers, rather than by "pointing off" so-and-so many places from

the right-hand end. For the right-hand figures of a number are the least important ones, and in many cases are entirely unknown (especially when the slide rule or a computing machine is used). The mental process for determining the decimal point is as follows:

(a) If the multiplier is a number like 3.1416, with only one figure preceding the decimal point, think of this number as "a little over 3;" then the product must be "a little over three times the number which is being multiplied;" and this gives the position of the decimal point at once, by inspection.

(b) If the multiplier is a number like 3141.6 [or 0.000 003 141 6], think of this number as "about 3, with the point moved three places to the right" [or "about 3, with the point moved six places to the left"]; then think what the answer would be if the multiplier were simply "about 3," and shift the decimal point accordingly.

Multiplication Tables. Crelle's large volume (Berlin, G. Reimer) gives the product of every three-figure number by every three-figure number; Peters's (Berlin, G. Reimer), of every four-figure number by every two-figure number. The smaller table of H. Zimmermann (Berlin, Wm. Ernst) gives the product of every three-figure number by every two-figure number.

Division. In long division, where the numbers are given only approximately, the work can be much abbreviated without loss of accuracy by "cutting off" one figure of the divisor at each step, instead of "bringing down" a doubtful zero in the dividend. Thus, 3.1416 + 2.3026 = 1.3644.

To determine the position of the decimal point in a problem of fractional division, shift the point (mentally) in both numerator and denominator (the same number of places in each) until the denominator is a number in the "standard form," that is, a number with only one figure preceding the decimal point. (This will not change the value

23026)31416(1 23026 2303) 8390(3 6909 230) 1481(6 1380 23) 101(4 92 2) 9(4

of the fraction.) Then estimate the approximate magnitude of the quotient by inspection. Thus:

$$\frac{0.2718}{3141.6} = \frac{0.000\ 2718}{3.1416} = \text{``about } 0.000\ 09\text{''} = 0.000\ 08652;$$

$$\frac{31.416}{0.002718} = \frac{31\ 416}{2.718} = \text{``about } 10\ 000\text{''} = 11\ 558.$$

Reciprocals. The reciprocal of N is 1/N. Instead of dividing by a long number N, it is often better to multiply by the reciprocal of N. The table of reciprocals on pp. 24-27 gives the reciprocal of any number, correct to four figures. Barlow's Table (Spon & Chamberlain, New York) gives the reciprocal of every four-figure number correct to seven figures (but without facilities for interpolation). The reciprocals of numbers having more than four figures are best found by the use of a large table of logarithms.

```
Reciprocals of 1 \pm x when x is Small.

1/(1+x) = 1 - x + [error < x^2, if x is between 0 and 1],
= 1 - x + x^2 - [error < x^3, if x is between 0 and 1].
1/(1-x) = 1 + x + [error < x^2 + 2x^3, if x is between 0 and 1],
= 1 + x + x^2 + [error < x^3 + 2x^4, if x is between 0 and 1].
```

Notation by Powers of 10. All questions concerning the position of the decimal point are readily answered if each number is expressed in the "standard form," that is, as the product of two factors, one of which is a number with only one figure preceding the decimal point, while the other is a positive or negative power of 10. Thus, 3.1416×10^3 means 3.1416 with the point moved three places to the right, that is, 3141.6. Again, 3.1416×10^{-6} means 3.1416 with the point moved six places to the left, that is, 0.0000031416. This notation by powers of 10 should always be used in dealing with very

large or very small numbers. Among electrical engineers its use is very

Square Root. (a) If four figures of the root are sufficient, take the answer directly from the table of square roots, pp. 12-15. (b) To obtain a root of six or seven figures from the table, use the formula: $\sqrt{N} = a + [(N-a^2)/2a]$ (approx.), where a is the nearest value of \sqrt{N} obtainable from the table, with three or four ciphers annexed. Here a^2 must be found exactly, by direct multiplication, so that at least three significant figures of the difference $N-a^2$ shall be known correctly; but this done, the division of $N-a^2$ by 2a should be carried to only three figures (logarithms or slide rule may be used).

NOTE. The simplest way to obtain any root of a seven-figure number correct to seven figures is to use a seven-place table of logarithms, if such a table is at hand.

Square Roots of $1 \pm x$ when x is Small.

NOTE. $1/(a \pm b) = (1/a)[1/(1 \pm x)]$, where x = b/a.

general, even for numbers of moderate size.

$$(1+x)^{\frac{1}{2}} = 1 + \frac{1}{2}x - [\text{error less than } \frac{1}{2}x^2 \text{ if } 0 < x < 1]$$

$$= 1 + \frac{1}{2}x - \frac{1}{2}x^2 + [\text{error } < \frac{1}{2}x^2 \text{ if } 0 < x < 1]$$

$$(1-x)^{\frac{1}{2}} = 1 - \frac{1}{2}x - [\text{error } < \frac{1}{2}x^2 + \frac{1}{2}x^3 \text{ if } 0 < x < \frac{1}{2}]$$

$$= 1 - \frac{1}{2}x - \frac{1}{2}x^2 - [\text{error } < \frac{1}{2}x^2 + \frac{1}{2}x^3 \text{ if } 0 < x < \frac{1}{2}]$$

$$\text{NOTE. } \sqrt{a+b} = \sqrt{a} (1+x)^{\frac{1}{2}}, \text{ where } x = b/a.$$

Cube Root. (a) If four figures of the root are sufficient, take the answer directly from the table of cube roots, pp. 16-21. (b) To obtain a root of six or seven figures from the table, use the formula: $\sqrt[3]{N} = a + [(N - a^3)/3a^3]$ (approx.), where a is the nearest value of $\sqrt[3]{N}$ obtainable from the table, with three or four ciphers annexed. Here a^3 must be found correct to seven or eight figures, by direct multiplication, so that at least three significant figures of the difference $N - a^3$ shall be known; but this done, the division of $N - a^3$ by $3a^2$ should be carried to only three or four figures (logarithms or the slide rule may be used).

NOTE. The simplest way to obtain any root of a seven-figure number correct to seven figures is to use a seven-place table of logarithms, if such a table is at hand.

Cube Roots of $1 \pm x$ when x is Small.

$$(1+x)^{\frac{1}{2}\delta} = 1 + \frac{1}{2}x - [\text{error} < \frac{1}{2}6x^2 \text{ if } 0 < x < 1],$$

$$= 1 + \frac{1}{2}x - \frac{1}{2}x^2 + [\text{error} < \frac{1}{2}6x^3 \text{ if } 0 < x < 1],$$

$$(1-x)^{\frac{1}{2}\delta} = 1 - \frac{1}{2}x - [\text{error} < \frac{1}{2}6x^2 + \frac{1}{2}6x^3 \text{ if } 0 < x < \frac{1}{2}],$$

$$= 1 - \frac{1}{2}x - \frac{1}{2}6x^2 - [\text{error} < \frac{1}{2}6x^3 + \frac{1}{2}6x^4 \text{ if } 0 < x < \frac{1}{2}].$$
Note. $\sqrt[3]{a+b} = \sqrt[3]{a(1+x)^{\frac{1}{2}\delta}}$, where $x = b/a$.

LOGARITHMS

Tables of Logarithms. The use of a table of logarithms greatly reduces the labor of multiplication, division, raising to powers, and extracting roots. The table on pp. 42-43 is carried out to four significant figures, and the following explanations should be sufficient to permit the use of the table readily, even by one without previous experience. For algebraic theory, see p. 113.

If more than four-figure accuracy is required, recourse must be had to a larger table. Five-place tables are available in great variety; the Macmillan Tables, 1913, are perhaps as convenient as any. If more than five figures are required, use Bremiker's six-place table, or proceed at once to a seven-place table: Schrön (Vieweg und Sohn, Braunsohweig); Bruhns; Vega-Bremiker. If extreme accuracy is required, use the eight-place table by Bauschinger and Peters (Engelmann, Leipzig). Logarithmic paper, see p. 176.

To Find the Logarithm of Any Given (Positive) Number.

(a) WHEN THE GIVEN NUMBER IS BETWEEN 1 AND 10.

An inspection of the table on pp. 42-43 shows that as the number increases from 1 to 9.99... the logarithm of that number increases continuously from 0 to 0.999... For example, log 2.97 = 0.4728; log 2.98 = 0.4742.

If the given number contains four significant figures, it is necessary to interpolate between the tabulated values, as follows:

To find log 2.973, notice that this number is $\frac{3}{10}$ of the way from 2.97 to 2.98; hence its logarithm will be (approximately) $\frac{3}{10}$ of the way from 0.4728 to 0.4742. The difference here is 14 units, and $\frac{3}{10}$ of this difference is 4 (to the nearest unit); hence, by adding this 4 to 4728, log 2.973 = 0.4732. This process of interpolating should be performed mentally; the step of finding the tabular difference will be facilitated by a glance at the last column on the right, which gives, for each line of the table, the average of the differences along that line.

Again, to find log 4.098: From table, $\log 4.09 = 0.6117$; adding $\frac{9}{10}$ of the difference (11), or about 9, gives: $\log 4.098 = 0.6126$. Or better, since $\frac{9}{10}$ of the way forward is equal to $\frac{9}{10}$ of the way back, find in table $\log 4.10 = 0.6128$, and subtract $\frac{9}{10}$ of 11, or 2, giving $\log 4.098 = 0.6126$. It should be noted that any interpolated value may be in error by 1 in the last place.

If the given number contains more than four significant figures, it should be cut down to four figures (see p. 88), since the later figures will not affect the result in four-place computations.

(b) When the Given Number is Less Than 1 or More Than 10, it is simply necessary to notice that every such number can be regarded as obtainable from some number between 1 and 10 by merely shifting the decimal point (see p. 90); and that according to the rule at the foot of the table, moving the decimal point n places to the right [or left] in the number-column is equivalent to adding n [or -n] to the logarithm in the body of the table.

For example, to find $\log 2973$. Here $2973 = 2.973 \times 10^3$ (i.e., 2.973 with the decimal point moved 3 places to the right). From the table, $\log 2.973 = 0.4732$. Hence, $\log 2973 = 0.4732 + 3$, which may be written as 3.4732.

Again, to find $\log 0.0002973$. Here $0.0002973 = 2.973 \times 10^{-4}$ (i.e., 2.973 with the decimal point moved 4 places to the left). From the table, $\log 2.973 = 0.4732$. Hence, $\log 0.0002973 = 0.4732 - 4$. (This may be written as 4.4732, if desired, and is equal of course, to -3.5268; this latter form, however, is not convenient in practice.)

It is thus evident that the logarithm of every positive number may be regarded as consisting of two parts: a decimal fraction, which is always positive (or zero); and a whole number, which may be positive, negative, or zero. The fractional part is called the **mantissa**, and is found from the table; the whole-number part is called the **characteristic**, and is determined by inspection.

To Find the Number Corresponding to a Given Logarithm.

(a) WHEN THE GIVEN LOGARITHM IS A POSITIVE DECIMAL FRACTION (CHARACTERISTIC ZERO), simply reverse the process for finding the logarithm of a number between 1 and 10.

For example, given $\log N = 0.4732$; to find N. In the body of the table it is seen that 0.4732 lies a little beyond 0.4728; hence N must lie a little beyond 2.97. By taking differences it is found that 4728 is in fact 9/4 of the way from 0.4728 to the next higher logarithm; therefore N must be 9/4 of the way from 2.97 to the next higher number. But 9/4 of 1 is 0.3 (to the nearest tenth), hence N = 2.973. Again, given $\log N = 0.6126$; to find N. Here, 0.6126 is 9/4 of the way from 0.6117

Again, given $\log N = 0.6126$; to find N. Here, 0.6126 is $\%_1$ of the way from 0.6117 to the next higher logarithm; therefore N must be $\%_1$ of the way from 4.09 to the next higher number. But $\%_1$ of 1 is 0.8 (to the nearest tenth), hence N = 4.098.

(b) When the given logarithm has any given value (characteristic not zero), proceed as follows: First, be sure the given logarithm is in the "standard form," that is, a positive decimal fraction (mantissa) plus a positive or negative whole number (characteristic). For example, if log N is originally given in the form $\log N = -3.5268$, this must first be reduced to the (equivalent) form $\log N = 0.4732 - 4$ (or 4.4732), before entering the table. Having the logarithm given in the standard form, suppose for the moment that the characteristic is zero, and find in the table the number corresponding to the given mantissa; then move the decimal point to the right or left according as the value of the characteristic is positive or negative.

For example, given $\log N = 0.4732 + 3$; to find N. From the table, the number corresponding to 0.4732 is 2.973. The characteristic (+3) directs that the decimal point be moved 3 places to the right; hence $N = 2.973 \times 10^3 = 2973$.

point be moved 3 places to the right; hence $N = 2.973 \times 10^3 = 2973$. Again, given $\log N = 0.4732 - 4$; to find N. From the table, the number corresponding to 0.4732 is 2.973. The characteristic (-4) indicates that the decimal point is to be moved 4 places to the left; hence $N = 2.973 \times 10^{-4} = 0.0002973$.

The number corresponding to a given logarithm is called its **antilogarithm**. Thus, if $\log 2973 = 0.4732 + 3$, then 2973 = antilog (0.4732 + 3).

NOTE 1. In most tables of logarithms the decimal point is omitted, the tables being in fact not tables of logarithms, but tables of mantissas. This omission is of no consequence to the experienced computer, but is often perplexing to one who makes only occasional use of such tables.

NOTE 2. Many computers prefer to write negative characteristics in the form of some positive number minus some multiple of 10; thus, 0.4732 - 4 = 6.4732 - 10; 0.4732 - 13 = 7.4732 - 20; etc.

Fundamental Properties of Logarithms. The usefulness of logarithms in computation depends on the following properties:

(1)
$$\log (ab) = \log a + \log b$$
; (3) $\log (a^n) = n \log a$;
(2) $\log (a/b) = \log a - \log b$; (4) $\log \sqrt[n]{a} = (1/n) \log a$;
(5) $\log 10^n = n$

It is to be noted also that $\log 1 = 0$, $\log 10 = 1$, and $\log (1/n) = -\log n$.

1

To Multiply by Logarithms. Find from the table the log. of each factor, and add; the result will be the log. of the product. Then find the product itself from the table.

```
EXAMPLE. To find \log 4.098 = 0.6126 x = (4.098)(0.0002973)(72.1). \log 0.0002973 = 0.4732 - 4 \log 72.1 = \frac{0.8579 + 1}{1.9437 - 3} = 0.9437 - 2.
```

To Divide by Logarithms. First Method: Find from the table the log. of the numerator and the log. of the denominator, and subtract the second from the first; the result will be the logarithm of the quotient. Then find the quotient itself from the table.

```
EXAMPLE. To find x = \frac{4.098}{0.0002973} log 4.098 = 0.6126 log 0.0002973 = 0.4732 - 4
Answer: x = 1.378 \times 10^4 = 13780 log x = 0.1394 + 4
```

In order to avoid negative mantissas in cases where a larger mantissa would have to be subtracted from a smaller, modify the upper logarithm by adding and subtracting 1.

EXAMPLE. To find
$$x = \frac{0.0291}{63.4}$$
. $\log 0.0291 = 0.4639 - 2 = 1.4639 - 3$ $\log 63.4 = 0.8021 + 1 = 0.8021 + 1$ $\log x = 0.0004590$.

To Divide by Logarithms. Second Method: Instead of subtracting the log. of a number, it is often convenient to add the cologarithm of that number; the colog. of N being defined by: $\operatorname{colog} N = \log(1/N) = -\log N$.

To find the colog. of a number, write the log. of the number in the standard form, and subtract it from 1.0000 - 1, as in the following examples:

This subtraction should be performed mentally. Thus, to subtract the mantissa, subtract each digit from 9 until the last non-zero digit is arrived at, and subtract this from 10; to subtract the characteristic, follow the regular rule of algebra ("reverse the sign and add"). Hence, if the logarithm itself is already written down, or can be read off from the table without interpolation, the cologarithm can be written down at once, by inspection. The use of cologarithms is not essential in logarithmic computation, but it often facilitates a compact arrangement of the work, especially in cases where the denominator of a fraction is itself the product of two or more factors.

To Find the nth Power of a Number by Logarithms. Find from the table the log. of the number, and multiply it by n; the result will be the logarithm of the nth power of that number. Then find the power itself from the tables.

EXAMPLE 1. Find
$$x = (0.0291)^3$$
 log $0.0291 = 0.4639 - 2$
Answer: $x = 2.464 \times 10^{-5}$
 $= 0.00002464$. log $x = 1.3917 - 6 = 0.3917 - 5$.

EXAMPLE 2. Find
$$x = (0.0291)^{1\cdot41}$$
 log $0.0291 = 0.4639 - 2 = -1.5361$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
 $= 0.006825$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
Answer: $x = 6.825 \times 10^{-3}$
An

To Find the nth Root of a Number by Logarithms. Find from the table the log. of the number, and divide it by n; the result will be the log. of the nth root of that number. Then find the root itself from the table.

EXAMPLE. Find
$$x = \sqrt[3]{4.098}$$
 log 4.098 = 0.6126
Answer: $x = 1.600$ log $x = 0.2042$

In order to avoid fractional characteristics, if the characteristic is not divisible by n, make it so divisible by adding and subtracting a suitable number before dividing.

EXAMPLE. Find
$$x = \sqrt[3]{0.0004590}$$
. log $0.0004590 = 0.6618 - 7$. Answer: $x = 7.714 \times 10^{-2}$ 3)2.6618 - 6 = 0.07714 log $x = 0.8873 - 2$

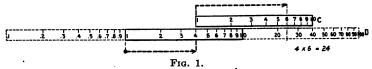

But if the characteristic is positive, it is simpler to write it in front of the mantissa, and then divide directly.

THE SLIDE RULE

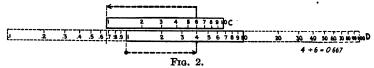

The slide rule is an indispensable aid in all problems in multiplication, division, proportion, squares, square roots, etc., in which a limited degree of accuracy is sufficient. The ordinary 10-in. Mannheim rule (see below) costs \$3 to \$4.50 and gives three significant figures correctly; the 20-in. rule (\$12.50) gives from three to four figures; the Fuller spiral rule (\$30) or the Thacher cylindrical rule (\$35) gives from four to five figures. For many problems the slide rule gives results more rapidly than a table of logarithms; it requires, however, more care in placing the decimal point in the answer. In all work with the slide rule, the position of the decimal point should be determined by inspection (see p. 89), only the sequence of digits being obtained from the instrument itself. Rapidity in the use of the instrument depends mainly on the skill with which the eye can estimate the values of the various divisions on the scale; expertness in this respect comes only with practice. The following explanations should be sufficient to permit the use of the ordinary slide rule successfully without previous experience and without knowledge of logarithms.

Multiplication and Division with a (Theoretical) Complete Logarithmic Scale. Consider a complete logarithmic scale $(D, \operatorname{Fig. 1})$, assumed to extend indefinitely in both directions, only the main section, from 1 to 10, however, being usually available. Note that the divisions within the several sections are indentical, except that the numeral attached to each division of any one section is ten times the numeral attached to the corresponding division in the preceding section. [The distances laid off from 1 are proportional to the logarithms of the corresponding numbers, the distance from 1 to 10 being taken as unity.] Consider also a duplicate scale, C, numbered from 1 to 10, and arranged to slide along the fixed scale D as in the figures. By means of such a scale D, and slide C, any two numbers between 1 and 10 (and hence any two numbers whatever, with proper attention to the decimal point) can be multiplied or divided, as in the following examples.

To MULTIPLY 4 BY 6. In Fig. 1, starting with point 1 of the fixed scale, run the eye along from 1 to 4; then set the 1 of the slide opposite this point 4, and run the eye forward along the slide from 1 to 6; the point thus reached on the fixed scale is 24, which is equal to 4×6 . This process gives the distance from 1 to 6, and is, in fact, a mechanical method of adding the logarithms of these numbers; hence the result is the product of the numbers. Conversely,

To DIVIDE 4 BY 6. In Fig. 2, starting with the point 1 of the fixed scale, run the eye along from 1 to 4; then set the 6 of the slide opposite the point 4, and run the eye backward along the slide from 6 to 1; the point thus reached on the fixed scale is 0.667, which is equal to $4 \div 6$. This process gives the distance from 1 to 4 minus the distance from 1 to 6; and is, in fact, a mechanical method of subtracting the logarithms of these numbers; hence the result is their quotient.

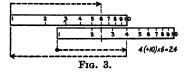

Multiplication and Division, Using Only a Single Section of the Scale. If only the main section of scale D is available (as is usually the case in practice), the result of multiplication may fall beyond the scale, as it does in Fig. 1. In such cases divide the first factor by 10 before beginning to multiply; this will bring the result within the scale, without affecting the sequence of digits.

For example, to multiply 4 by 6. Having found that the setting shown in Fig. 1 is not successful, reset the slide as in Fig. 3, with 10 instead of 1 opposite 4; run the eye backward along the slide from 10 to 1, thus reaching the (unrecorded) point corresponding to 4 + 10; then, continuing from this point, run the eye forward along the slide from 1 to 6, as before; the point finally reached on the main scale is 2.4, which has the same sequence of digits as the required value 24. After a little practice, this preliminary step of dividing by 10 will be performed almost intuitively. Whether or not this step is necessary in any given case, can be determined only by trial.

The general rule for multiplication may be stated as follows, if preferred: To find the product of two factors, find one factor on the fixed scale; opposite this, set (tentatively) point 1 of the slide; on the slide find the second factor, and opposite this read the product on the main scale, if possible. If the product falls beyond the scale, begin over again, using point 10 of the slide instead of point 1.

In division also, the result may fall beyond the main section of the scale, as it does in Fig. 2. In such cases, it suffices merely to multiply the result by 10 in order to bring it within the scale; this will not affect the sequence of digits.

For example, to divide 4 by 6, set the slide as in Fig. 4, and follow out mentally the steps indicated by the arrows. It will be noticed that the supplementary step of multiplying by 10 is performed by simply running the eye along the slide from 1 to 10 without resetting the slide; for this reason, division on the slide rule is slightly easier than multiplication.

The Ordinary Mannheim Slide Rule has four scales, A, B, C, D, as shown in Fig. 5. Scales C and D are essentially the same as the C and D scales described above, and the principle just explained shows how they are used in multiplication and division. The fact that the D scale covers only the main section from 1 to 10 (all decimal points being omitted) is practically no restriction on the scope of the scale, as is seen in the preceding examples. A runner is provided, so that intermediate positions reached in the course of an extended computation may be indicated temporarily on the scale without the necessity of reading off their numerical values. The best runners are those which have no side frame to obscure the numerals.

In problems involving successive multiplications and divisions, arrange the work so that multiplication and division are performed alternately.

For example, to calculate $\frac{a \times b \times c}{d \times e}$, divide the product $a \times b$ by d; multiply this quotient by c; and divide this product by e. Each operation will require only one shifting either of the slide (for multiplication) or of the runner (for division).

To multiply a number of different quantities by a constant multiplier, x, set the point 1 of slide opposite x, and read, by aid of the runner, the products of x by all the quantities which do not fall beyond the scale; then reset the slide, setting 10 instead of 1 opposite x, and read the products of x by all the remaining quantities.

To divide a number of different quantities by a constant divisor, y, first find (by the slide rule) the quotient 1 + y, and then use this as a constant multiplier.

Scales A and B are exactly like scales C and D, except that they cover two sections of the complete logarithmic scale, the graduations being only half as fine. Either pair of scales may be used for multiplication and division; C and D give more accurate readings, but have the disadvantage that in the case of multiplication the slide must often be shifted to the other end in order to keep the result on the scale—an inconvenience which is not present when the less accurate scales A and B are employed.

By the use of both pairs of scales, problems in squares and square roots may be readily solved; for every number on A, except for the decimal point, is the square of the number directly below it on D (use the runner).

A scale of sines, tangents, and logarithms is often printed on the back of the slide. For further details concerning the use of the slide rule in various problems, see the instruction books furnished with each instrument: Wm. Cox, "Manual of the Mannheim Slide Rule;" F. A. Halsey, "Manual of the Slide Rule;" etc.

Other Types of Slide Rules. The duplex slide rule (\$5 to \$18 according to length) shows on one face the regular A, B, C, D scales, and on the other face the scales A, B', C', D (where B' and C' are the same as B and C, only numbered in the reverse order), with a runner encircling the whole scale. This arrangement makes possible the solution of more complicated problems with fewer settings of the slide, but if the rule is to be used only for simple problems, the multiplicity of scales is rather confusing. Less complicated is the polyphase rule, which is like a Mannheim rule with the addition of a single inverted scale, C', printed in the middle of the slide. The log log duplex slide rule (10 in., \$8) is especially adapted for handling complex problems involving fractional powers or roots, hyperbolic logarithms, etc. A number of circular slide rules are on the market, the best of which are operated by a milled thumbnut, like the stem wind of a watch. The advantage of the circular rule, aside from its comnact size (some models are scarcely larger than a watch), lies in the fact that the scale is endless, so that the slide never has to be reset in order to bring the result within the scale. A disadvantage is found in the necessity of reading the figures in oblique positions, or else continually turning the instrument as a whole in the hand. The Fuller and Thacher rules already mentioned are invaluable for problems requiring greater accuracy than can be obtained with the ordinary rules. There are also many special slide rules, adapted to various special types of computation, such as calculating discharge of water through pipes, horse power of engines, dimensions of lumber, stadia measurements, etc. One of the most recent devices of this kind is the Ross meridiograph (L. Ross, San Francisco, Cal.), which is a circular slide rule for solving certain cases of spherical triangles. The Eichhorn trigonometrical slide rule solves any plane triangle.

COMPUTING MACHINES

For certain purposes computing machines have ceased to be luxuries and have become almost necessities; but they are expensive, and should be selected with reference to the special work which is to be done. The machines may be classified roughly into three groups, as follows:

Adding Machines, Non-listing. Of the machines of this kind, the most convenient in the hands of a careful operator is the well-known Comptometer (Felt & Tarrant Co., Chicago, Ill.; \$250 to \$350 according to size), or the recent Burroughs non-listing adding machine (Detroit, Mich., \$175). To add a number, simply press a key in the proper column; the result appears on the dials in front of the keyboard. Multiplication as well as addition can be performed on this machine with great rapidity, and division also after a little practice. Weight, about 15 lb. Much less rapid, but less expensive and requiring somewhat less skill in operation, is the Barrett adding machine (Philadelphia, Pa.) with multiplying attachment. Other key-operated machines are the Mechanical Accountant (Providence, R. I.), and the Austin (Baltimore, Md.). The American adding machine (American Can Co., Chicago, III.; \$39.50) is operated by pulling up a finger-lever for each digit. Small machines, operated by the use of a stylus, are the Rapid computer (Benton Harbor, Mich., \$25); the Gem (Automatic Adding Machine Co., New York; \$10), the Arithstyle (New York, \$36) and the Triumph (Brooklyn, N. Y., \$35). These machines, while much less rapid than the key-operated machines, are useful in simple addition. The Underwood typewriter is now supplied with a complete electrically driven adding machine attached, and the Wahl adding attachment is supplied on the Remington and other typewriters. Ray Subtracto-Adder (Richmond, Va., \$25).

Adding and Listing Machines. The machines of this group not only add, but also print the items, totals and sub-totals. The Burroughs (Detroit, Mich.), the Wales (Adder Machine Co., Wilkes-Barre, Pa.), the Comptograph (Chicago, Ill.) and the White (New Haven, Conn.), resemble each other in having an 81-key keyboard; the Dalton (Cincianati, Ohio) and the Commercial (White Adding Machine Co., New Haven,

Conn.) have a 10-key and a 9-key keyboard respectively, admitting of operation by the touch method. On all these machines, in order to add a number, first depress the proper keys and then pull a handle (or, in the case of electrically driven machines, press a button) to record the item. Multiplication cannot be performed conveniently, except on the Dalton. Subtraction can be performed only by adding the complement, except on the Commercial and on one type of the Burroughs. The prices range from \$125 to \$600, according to size and style, new models being constantly devised for special commercial purposes. A new and more portable machine of the 81-key type is the Barrett adding and listing machine (Philadelphia, Pa., \$250). A cheaper machine, with a 10key keyboard, is the Standard (St. Louis, Mo.). The new American adding and listing machine (American Can Co., Chicago, Ill.), operated by pulling up a finger-lever for each digit, costs only \$88. The Ellis (Newark, N. J.) is an elaborate adding and listing machine having a complete typewriter incorporated with it. The Elliott-Fisher bookkeeping machine (Harrisburg, Pa.) and the Moon-Hopkins billing machine (St. Louis, Mo.) are intended primarily for commercial use; the latter is a complicated electric machine (\$750) which combines many of the features of an adding and listing machine with those of a calculating machine.

Calculating Machines (so-called). Machines of this third group are intended primarily for multiplication and division; the types which have a keyboard can be used effectively for addition and subtraction also. They are all non-listing. The earliest commercially successful types were the Thomas and the Brunsviga. In both these types the multiplicand is set up by moving pegs in slots, or (in the newest models) by depressing keys, and the multiplication is effected by turning a handle for each digit of the multiplier—twice for a digit 2, three times for a digit 3, etc.; the result then appears on the dials. In the Thomas type the handle always turns in the same direction, the change from multiplication to division being effected by a shift key. In the Brunsviga type the handle is turned forward for multiplication and backward for division. Among the best examples of the Thomas type now on the American market are the Tim, with a single row of dials, the Unitas, with a double row of dials (both sold by Oscar Müller Co., New York City; also with keyboard and electric drive), and the Reuter (Philadelphia, Pa.). Prices, \$300 upward. Another machine of this type, with keyboard, is the Record (U. S. Adding Machine Co., New York City). Brunsviga is represented by Carl H. Reuter, Philadelphia, Pa.; various models. Of somewhat similar type are the Triumphator (New York City; \$250), and Colt's calculator (Culmer Engineering Co., New York City). A new machine, on the same principle, but with keyboard, is the Monroe (made in Orange, N. J.; \$250). The Millionaire (W. A. Morschhauser, New York City; \$400), is from the mechanical point of view, the only true multiplying machine on the market (except the Moon-Hopkins). After the multiplicand is set up on the pegs, the digits of the multiplier are indicated successively by moving a pointer, the handle being turned only once for each digit. Further, the movement of the carriage is automatic. The newest models have keyboard and electric drive. The Ensign electric calculating machine (Boston, Mass.; \$400) is a new machine with an 81-key keyboard on which it adds like an adding machine, and a secondary 10-key keyboard by means of which it multiplies and divides quite as rapidly as any of the calculating machines, the proper key being pressed just once for each digit of the multiplier. The National calculator (New York), and the Lamb calculator (Calculator Mfg. Co., New York) are less expensive machines devised for figuring payrolls and labor costs. A still simpler device for the same purpose is the Calculacard (New York). The machine called the Calculagraph (New York) is a time clock which automatically computes labor costs. For graphical methods of computation, see pp. 106, 119, 170, 173-185.

FINANCIAL ARITHMETIC

For the facts which are commonly required in regard to compound interest, sinking funds, etc., see the headings of the tables on pp. 64-68.

ELEMENTARY GEOMETRY AND MENSURATION

GEOMETRICAL THEOREMS

(For geometrical constructions, see p. 101)

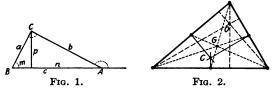

Right Triangles. $a^2 + b^2 = c^2$. (See Fig. 1). $\angle A + \angle B = 90^\circ$. $p^2 = mn$. $a^2 = mc$. $b^2 = nc$. See also p. 105 and p. 132.

Oblique Triangles. (See also pp. 105, 134.) Sum of angles = 180°. An exterior angle = sum of the two opposite interior angles. (Fig. 1.)

The medians, joining each vertex with the middle point of the opposite side, meet in the center of gravity G (Fig. 2), which trisects each median.

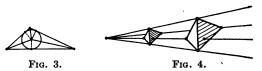

The altitudes meet in a point called the orthocenter, O.

The perpendiculars erected at the midpoints of the sides meet in a point C, the center of the circumscribed circle. [In any triangle G, O, and C lie in line, and G is two-thirds of the way from O to C.]

The bisectors of the angles meet in the center of the inscribed circle (Fig. 3).

The largest side of a triangle is opposite the largest angle; it is less than the sum of the other two sides, and greater than their difference.

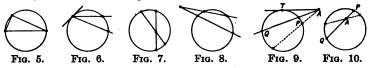

Similar Figures. Any two similar figures, in a plane or in space, can be placed in "perspective," that is, so that straight lines joining corresponding points of the two figures will pass through a common point (Fig. 4). That is, of two similar figures, one is merely an enlargement of the other. Assume that each length in one figure is k times the corresponding length in the other; then each area in the first figure is k^2 times the corresponding area in the second, and each volume in the first figure is k^3 times the corresponding volume in the second. If two lines are cut by a set of parallel lines (or parallel planes), the corresponding segments are proportional.

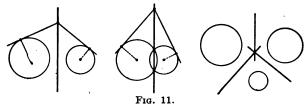

The Circle. (See also pp. 106, 137.) An angle inscribed in a semicircle is a right angle (Fig. 5). An angle inscribed in a circle, or an angle between a chord and a tangent, is measured by half the intercepted arc (Fig. 6). An angle formed by any two lines which meet a circle is measured by half the sum or half the difference of the intercepted arcs, according as the point of intersection of the lines lies inside (Fig. 7) or outside the circle (Fig. 8).

A tangent is perpendicular to the radius drawn to the point of contact. If a variable line through A (Figs. 9 and 10) cuts a circle in P and Q, then

 $\overline{AP} \times \overline{AQ}$ is constant; in particular, if A is an external point, $\overline{AP} \times \overline{AQ} = \overline{AT}$, where \overline{AT} is the tangent from A.

The radical axis (Fig. 11) of two circles is a straight line such that the tangents drawn from any point of this line to the two circles are of equal length. If the two circles intersect, the radical axis passes through their points of intersection. In any case, the radical axis bisects the common tangents of the two circles. The three radical axes of a set of three circles meet in a common point. (For equations, see p. 137.)

Dihedral Angles. The dihedral angle between two planes is measured by a plane angle formed by two lines, one in each plane, perpendicular to the edge (Fig. 12). (For solid angles, see p. 110.)

In a tetrahedron, or triangular pyramid, the four medians, joining each vertex with the center of gravity of the opposite face, meet in a point, the center of gravity of the tetrahedron; this point is ¾ of the way from any vertex to the center of gravity of the opposite face. The four perpendiculars erected at the circumcenters of the four faces meet in a point, the center of the circumscribed sphere. The four altitudes meet in a point called the orthocenter of the tetrahedron. The planes bisecting the six dihedral angles meet in a point, the center of the inscribed sphere.

Regular Polyhedra (see also p. 110): Regular tetrahedron (Fig. 13), bounded by four equilateral triangles; cube (Fig. 14), bounded by six squares; octahedron (Fig. 15), bounded by eight equilateral triangles; dodecahedron (Fig. 16), bounded by twelve regular pentagons; icosahedron (Fig. 17), bounded by twenty equilateral triangles. Figs. 13-17 show how these solids can be made by cutting the surface out of paper and folding it together.

The Sphere. (See also p. 109.) If AB is a diameter, any plane perpendicular to AB cuts the sphere in a circle, of which A and B are called the poles. A great circle on the sphere is formed by a plane passing through the center. A spherical triangle is bounded by arcs of great circles (see p.

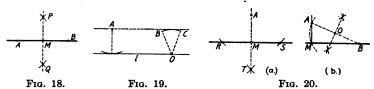

134). In two polar triangles, each angle in one is the supplement of the corresponding side in the other. In two symmetrical triangles, the sides and angles of one are equal to the corresponding sides and angles of the other, but arranged in the reverse order (like right-handed and left-handed gloves).

GEOMETRICAL CONSTRUCTIONS

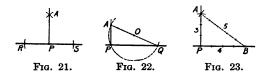

To Bisect a Line AB (Fig. 18). (a) From A and B as centers, and with equal radii, describe arcs intersecting in P and Q, and draw PQ, which will bisect AB in M.

(b) Lay off AC = BD = approximately half of AB, and then bisect CD.

To Draw a Parallel to a Given Linel Through a Given Point A (Fig. 19). With point A as center draw an arc just touching the line l; with any point O of the line as center, draw an arc BC with the same radius. Then a line through A touching this arc will be the required parallel. Or, use a straight edge and triangle. Or, use a sheet of celluloid with a set of lines parallel to one edge and about $\frac{1}{4}$ in. apart ruled upon it.

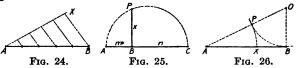

To Draw a Perpendicular to a Given Line from a Given Point \mathbb{A} Outside the Line (Fig. 20). (a) With A as center, describe an arc cutting the line in R and S, and bisect RS in M. Then M is the foot of the perpendicular. (b) If A is nearly opposite one end of the line, take any point B of the line and bisect AB in O; then with O as center, and OA or OB as radius, draw an arc cutting the line in M. Or, (c) use a straight edge and triangle.

To Erect a Perpendicular to a Given Line at a Given Point P. (a) Lay off PR = PS (Fig. 21), and with R and S as centers draw arcs intersecting at A. Then PA is the required perpendicular. (b) If P is near the end of the line, take any convenient point O (Fig. 22) above the line as center, and with radius OP draw an arc cutting the line in Q. Produce QO to meet the arc in A; then PA is the required perpendicular. (c) Lay off PB = 4 units of any scale (Fig. 23); from P and B as centers lay off PA = 3 and BA = 5; then APB is a right angle.

To Divide a Line AB into n Equal Parts (Fig. 24). Through A draw a line AX at any angle, and lay off n equal steps along this line. Connect the last of these divisions with B, and draw parallels through the other divi-

sions. These parallels will divide the given line into n equal parts. A similar method may be used to divide a line into parts which shall be proportional to any given numbers.

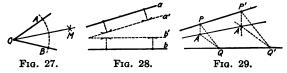

To Construct a Mean Proportional (or Geometric Mean) Between Two Lengths, m and n (Fig. 25). Lay off AB = m and BC = n and construct a semicircle on AC as diameter. Let the perpendicular erected at B meet the circumference at P. Then $BP = \sqrt{mn}$. (See p. 115.)

To Divide a Line AB in Extreme and Mean Ratio (the "golden section"). At one end, B, of the given line (Fig. 26), erect a perpendicular, BO, equal to half AB, and join OA. Along OA lay off OP = OB, and along AB lay off AX = AP. Then X is the required point of division; that is, $\overline{AX^2} = AB \times BX$. Numerically, $AX = \frac{1}{2}(\sqrt{5} - 1)(AB) = 0.618(AB)$.

To Bisect an Angle AOB (Fig. 27). Lay off OA = OB. From A and B as centers, with any convenient radius, draw arcs meeting in M; then OM is the required bisector.

To draw the bisector of an angle when the vertex of the angle is not accessible (Fig. 28). Parallel to the given lines a, b, and equidistant from them, draw two lines a', b' which intersect; then bisect the angle between a' and b'.

To Draw a Line Through a Given Point A and in the Direction of the Point of Intersection of Two Given Lines, when this point of intersection is inaccessible (Fig. 29). Draw any two parallel lines PQ and P'Q' as in the figure; through P' draw a line parallel to PA, and through Q' draw a line parallel to QA; let these lines intersect in A', and draw the line AA'. This line AA' will (if produced) pass through the intersection of the two given lines.

To Construct, Approximately, the Length of a Circular Arc (Rankine). In Fig. 30 draw a tangent at A. Prolong the chord BA to C, making AC =

14 AB. With C as center, and radius CB, draw arc cutting the tangent in D. Then $AD = \operatorname{arc} AB$, approximately (error about 4 min. in an arc of 60 deg.). Conversely, to find an arc AB on a given circle to equal a given length AD, take E one-fourth of the way from A to D, and with E as center and radius ED draw an arc cutting the circumference in B. Then arc AB = AD, approximately.

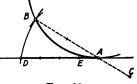

Fig. 30.

To Inscribe a Hexagon in a Circle (Fig. 31). Step around the circumference with a chord equal to the radius. Or, use a 60-deg. triangle.

To Circumscribe a Hexagon About a Circle (Fig. 32). Draw a chord AB equal to the radius. Bisect the arc AB in T. Draw the tangent at T (parallel to AB), meeting OA and OB in P and Q. Then draw a circle with radius OP or OQ and inscribe in it a hexagon, one side being PQ.

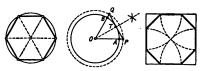

Fig. 31. Fig. 32. Fig. 33.

To Inscribe an Octagon in a Square (Fig. 33). From the corners as centers, and with radius equal to half the diagonal, draw four arcs, cutting the sides in eight points. The points will be the vertices of the octagon.

To Inscribe an Octagon in a Circle. Draw two perpendicular diameters, and bisect each of the quadrant arcs.

To Circumscribe an Octagon About a Draw a square about the circle, and draw the tangents to the circle at the points where the circle is cut by the diagonals of the square.

To Construct a Polygon of n Sides, One Side AB being Given (Fig. 34). With A as center and AB as radius, draw a semicircle,

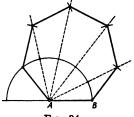

Fig. 34.

and divide it into n parts, of which n-2 parts (counting from B) are to be Draw rays from A through these points of division, and complete the construction as in the figure (in which n = 7). Note that the center of the polygon must lie in the perpen-

dicular bisector of each side.

To Draw a Tangent to a Circle from an external point A (Fig. 35). Bisect AC in M; with M as center and radius MC, draw are cutting circle in P; then P is the required point of tangency.

Fig. 35.

Fig. 36.

To Draw a Common Tangent to Two Given Circles (Fig. 36). Let C and c be the centers and R and r the radii (R > r). From C as center, draw

two concentric circles with radii R + rand R-r; draw tangents to these circles from c; then draw parallels to these lines at distance r. These parallels will be the required common tangents.

To Draw a Circle Through Three Given Points A. B. C. or to find the center of a given circular arc (Fig. 37). Draw the perpendicular bisectors of

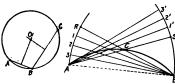

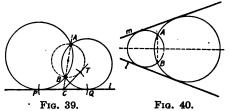

Fig. 37. Fig. 38.

AB and BC; these will meet in the center, O.

To Draw a Circular Arc Through Three Given Points When the Center is not Available (Fig. 38). With A and B as centers, and chord AB as radius, draw arcs, cut by BC in R and by AC in S. Divide RA into n equal parts, 1, 2, 3, . . . Divide BS into the same number of equal parts, and continue these divisions at 1', 2', 3', . . . Connect A with 1', 2', 3', . . .

and B with 1, 2, 3, . . . Then the points of intersection of corresponding lines will be points of the required arc. (Construction valid only when CA = CB.)

To Draw a Circle Through Two Given Points, A, B, and Touching a Given Line, 1 (Fig. 39). Let AB meet line lin

C. Draw any circle through A and B, and let CT be tangent to this circle from C. Along l, lay off CP and CQ equal to CT. Then either P or Q is the required point of tangency. (Two solutions.) Note that the center of the required circle lies in the perpendicular bisector of AB.

To Draw a Circle Through One Given Point, A, and Touching Two Given Lines, 1 and m (Fig. 40). Draw the bisector of the angle between l and m, and let B be the reflection of A in this line. Then draw a circle through A and B and touching l (or m), as in preceding construction. (Two solutions.)

To Draw a Circle Touching Three Given Lines (Fig. 41). Draw the bisectors of the three angles; these will meet in the center O. (Four solutions.) The perpendiculars from O to the three lines give the points of tangency.

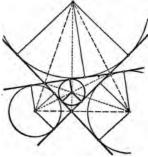

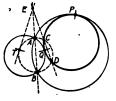

Fig. 41.

To Draw a Circle Through Two Given Points A, B, and Touching a Given Circle (Fig. 42). Draw any circle through A and B, cutting the given circle in C and D. Let AB and CD meet in E, and let ET be tangent

from E to the circle just drawn. With E as center, and radius ET, draw an arc cutting the given circle in P and Q. Either P or Q is the required point of contact. (Two solutions.)

To Draw a Circle Through One Given Point, A, and Touching Two Given Circles (Fig. 43). Let S be a center of

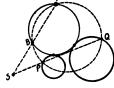

Fig. 42.

Fig. 43.

similitude for the two given circles, that is, the point of intersection of two external (or internal) common tangents. Through S draw any line cutting one circle in two points, the nearer of which shall be called P, and the other in two points, the more remote of which shall be called P. Through P, P, P

draw a circle cutting SA in B. Then draw a circle through A and B and touching one of the given circles (see preceding construction). This circle will touch the other given circle also. (Four solutions.)

To Draw an Annulus Which Shall Contain a Given Number of Equal

Contiguous Circles (Fig. 44). (An annulus is a ring-shaped area enclosed between two concentric circles.) Let R + r and R - r be the inner and outer radii of the annulus, r being the radius of each of the n circles. Then the required relation between these quantities is given by $r = R \sin(180^{\circ}/n)$, or $r = (R + r)[\sin(180^{\circ}/n)]/[1 + \sin(180^{\circ}/n)]$

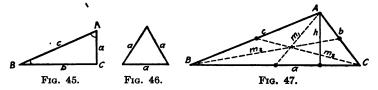

For methods of constructing ellipses and other curves, see pp. 139-156.

LENGTHS AND AREAS OF PLANE FIGURES

Right Triangle (Fig. 45). $a^2 + b^2 = c^2$. Area = ½ $ab = ½a^2 \cot A = ½b^2 \tan A = ½c^2 \sin 2A$.

Equilateral Triangle (Fig. 46). Area = $\frac{1}{3}a^2\sqrt{3}$ = 0.43301 a^2 .

Any Triangle (Fig. 47). $s = \frac{1}{2}(a + b + c), t = \frac{1}{2}(m_1 + m_2 + m_3),$

 $r = \sqrt{(s-a)(s-b)(s-c)/s}$ = radius inscribed circle,

 $R = \frac{1}{2} a / \sin A = \frac{1}{2} b / \sin B = \frac{1}{2} c / \sin C = \text{radius circumscribed circle};$

Area = $\frac{1}{2}$ base \times altitude = $\frac{1}{2}ah$ = $\frac{1}{2}ab$ sin C = rs = abc/4R

 $= \sqrt{s(s-a)(s-b)(s-c)} = \frac{1}{2} \sqrt{t(t-m_1)(t-m_2)(t-m_3)}$ = $r^2 \cot \frac{1}{2} A \cot \frac{1}{2} B \cot \frac{1}{2} C = 2R^2 \sin A \sin B \sin C$

 $= \pm \frac{1}{2} \{ (x_1y_2 - x_2y_1) + (x_2y_2 - x_2y_2) + (x_2y_1 - x_1y_2) \}, \text{ where}$

 $(x_1, y_1), (x_2, y_2), (x_3, y_2)$ are co-ordinates of vertices. See also p. 134.

Rectangle (Fig. 48). Area = $ab = \frac{1}{2}D^2 \sin u$. [u = angle between diagonals D, D.]

Rhombus (Fig. 49). Area = $a^2 \sin C = \frac{1}{2}D_1D_2$. [C = angle between two adjacent sides; D_1 , D_2 = diagonals.]

Parallelogram (Fig. 50). Area = $bh = ab \sin C = \frac{1}{2}D_1D_2 \sin u$. $[u = angle between diagonals <math>D_1$ and D_2 ; $D_1^2 + D_2^2 = 2(a^2 + b^2)$].

Trapesoid (Fig. 51). Area = $\frac{1}{2}(a + b)h = \frac{1}{2}D_1D_2 \sin u$. [Bases a and b are parallel; u = angle between diagonals D_1 and D_2 .]

Quadrilateral Inscribed in a Circle (Fig. 52). Area = $\frac{1}{2}D_1D_2 \sin u =$ $\sqrt{(s-a)(s-b)(s-c)(s-d)} = \frac{1}{2}(ac+bd)\sin u; \quad s = \frac{1}{2}(a+b+c+d).$ Any Quadrilateral (Fig. 53). Area = $\frac{1}{2}D_1D_2$ sin u.

Note. $a^2 + b^2 + c^2 + d^2 = D_1^2 + D_2^2 + 4m^2$, where m = distance betweenmidpoints of D_1 and D_2 .

Polygons. See table, p. 39.

Fig. 52.

Fig. 53.

F1g. 55.

Circle. Area = $\pi r^2 = \frac{1}{2}Cr = \frac{1}{2}Cd = \frac{1}{2}\pi d^2 = 0.785398d^2$ (table, p. 30). Here r = radius, d = diam., $C = \text{circumference} = 2\pi r = \pi d$ (table, p. 28). **Annulus** (Fig. 54). Area = $\pi(R^2 - r^2) = \pi(D^2 - d^2)/4 = 2\pi R'b$, where

 $R' = \text{mean radius} = \frac{1}{2}(R + r)$, and b = R - r.

Sector (Fig. 55). Area = $\frac{1}{2}rs = \pi r^2(A/360^\circ) =$ $\frac{1}{2}r^2$ rad A, where rad A = radian measure of angle A, and s = length of arc = r rad A (table, p. 44).

Segment (Fig. 56). Area = $\frac{1}{2}r^2$ (rad $A - \sin A$) = $\frac{1}{2}[r(s-c)+ch]$, where rad A = radian measure of angle A (table, pp. 34-35, 44). For small arcs, $s = \frac{1}{2}(8c'-c)$, where c' = chord of half the arc.(Huygens's approximation.) Note. $c = 2\sqrt{h(d-h)}$;

 $c' = \sqrt{dh}$ or $d = c'^2/h$, where d = diameter of circle; $h = r (1 - \cos \frac{1}{2}A), s = 2r \operatorname{rad} \frac{1}{2}A.$

Ribbon bounded by two parallel curves (Fig. 57). If a straight line AB moves so that it is always per-

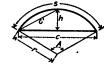

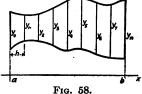

Fig. 56.

Fig. 57.

pendicular to the path traced by its middle point G. then the area of the ribbon or strip thus generated is equal to the length of AB times the length of the path traced by G. (It is assumed that the radius of curvature of G's path is never less than $\frac{1}{2}AB$, so that successive positions of the generating line will not intersect.)

Simpson's Rule (Fig. 58). Divide the given area into n panels (where n is some even number) by means of n + 1 parallel lines, called ordinates, drawn at constant distance h apart; and denote the lengths of these ordinates by y_0 , y_1 , y_2 , . . , y_n . (Note that y_0 or y_n may be zero.) Then Area = $\frac{1}{2}h[(y_0 + y_n) + 4(y_1 + y_3 + y_5...)]$

 $+2(y_2+y_4+y_6...)$], approx. The greater the number of divisions, the more accurate the result. Note: Taking y = f(x), where x varies from x = a to x = b, and h = (b - a)/n, then the $\frac{1}{80} \frac{(b-a)^5}{n^4} f''''(X)$, where f''''(X) is the value of the fourth derivative of f(x) for some (unknown) value, x = X, between a and b.

Ellipse (Fig. 59; see also p. 140). Area of ellipse = πab . Area of shaded segment = $xy + ab \sin^{-1}(x/a)$. Length of perimeter of ellipse = $\pi(a + b)K$, where $K = \begin{bmatrix} 1 + \frac{1}{2}m^2 + \frac{1}{2}64m^4 + \frac{1}{2}6sm^6 + \dots \end{bmatrix}$, m = (a - b)/(a + b). For $m = 0.1 \quad 0.2 \quad 0.3 \quad 0.4 \quad 0.5 \quad 0.6 \quad 0.7 \quad 0.8 \quad 0.9 \quad 1.0 \quad K = 1.002 \quad 1.010 \quad 1.023 \quad 1.040 \quad 1.064 \quad 1.092 \quad 1.127 \quad 1.168 \quad 1.216 \quad 1.273$

Fig. 59.

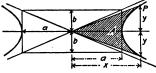

Fig. 60.

Hyperbola (Fig. 60; see also p. 144). In any hyperbola, shaded area $A = ab \log_a \left(\frac{x}{a} + \frac{y}{b}\right)$. In an equilateral hyperbola (a = b), area $A = a^2 \sinh^{-1}(y/a) = a^2 \cosh^{-1}(x/a)$. For tables of hyperbolic functions, see p. 60. Here x and y are co-ordinates of point P.

Parabola (Fig. 61; see also p. 138). Shaded area $A = \frac{1}{2}ch$. In Fig. 62, length of arc $OP = s = \frac{1}{2}PT + \frac{1}{2}p \log_e \cot \frac{1}{2}u$. Here c = any chord; p = semi-latus rectum; PT = tangent at P. Note: OT = OM = x.

Fig. 61.

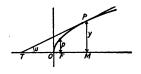

Fig. 62.

Other Curves. For lengths and areas, see pp. 147-156.

SURFACES AND VOLUMES OF SOLIDS

Regular Prism (Fig. 63). Volume = $\frac{1}{2}nrah = Bh$. Lateral area = nah = Ph. Here n = number of sides; B = area of base; P = perimeter of base. **Right Circular Cylinder** (Fig. 64). Volume = $\pi r^2h = Bh$. Lateral area = $2\pi rh = Ph$. Here B = area of base; P = perimeter of base.

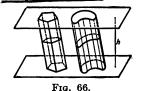

Fra 6

Fig. 64.

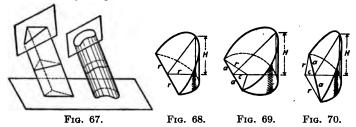

Fig. 65.

Truncated Right Circular Cylinder (Fig. 65). Volume $= \pi r^2 h = Bh$. Lateral area $= 2\pi r h = Ph$. Here $h = \text{mean height} = \frac{1}{2}(h_1 + h_2)$; B = area of base; P = perimeter of base.

Any Prism or Cylinder (Fig. 66). Volume = Bh = Nl. Lateral area = Ql. Here l =length of an element or lateral edge; B =area of base; N =area of normal section; Q =perimeter of normal section.

Any Truncated Prism or Cylinder (Fig. 67). Volume = Nl. Lateral area = Qk. Here l = distance between centers of gravity of areas of the two bases; k = distance between centers of gravity of perimeters of the two bases; N = area of normal section; Q = perimeter of normal section. For a truncated triangular prism with lateral edges a,b,c, l=k+2l(a+b+c). Note: l and k will always be parallel to the elements.

Special Ungula of a right circular cylinder. (Fig. 68.). Volume = $\frac{2}{3}r^2H$. Lateral area = 2rH. r = radius. (Upper surface is a semi-ellipse.)

Any Ungula of a right circular cylinder. (Figs. 69 and 70.) Volume = $H(3/a^3 \pm cB)/(r \pm c) = H[a(r^2 - 1/a^2) \pm r^2 c \operatorname{rad} u]/(r \pm c)$. Lateral area = $H(2ra \pm cs)/(r \pm c) = 2rH(a \pm c \operatorname{rad} u)/(r \pm c)$. If base is greater (less) s = arc of base; u = half the angle subtended by arc s at center; rad u = radian measure of angle u (see table, p. 44).

Hollow Cylinder (right and circular). Volume = $\pi h(R^2 - r^2) = \pi hb(D - b)$ = $\pi hb(d + b) = \pi hbD' = \pi hb$ (R + r). Here $h = \pi hb$ (R + r). Here $h = \pi hb$ (attitude; $r_iR(d_iD) = \pi hb$ outer radii (diameters); $h = \pi hb$ (diameters); $h = \pi hb$ (diameters) = hb

Regular Pyramid (Fig. 71). Volume = ½ altitude

Fig. 71.

Fig. 72.

Fig. 73.

 \times area of base = $\frac{1}{2}hran$. Lateral area = $\frac{1}{2}$ slant height \times perimeter of base = $\frac{1}{2}san$. Here r = radius of inscribed circle; a = side (of regular polygon); n = number of sides; $s = \sqrt{r^2 + h^2}$. Vertex of pyramid directly above center of base.

Right Circular Cone. Volume = $\frac{1}{2}\pi r^2h$. Lateral area = πrs . Here r = radius of base; h = altitude; s = slant height = $\sqrt{r^2 + h^2}$.

Frustum of Regular Pyramid (Fig. 72).

Volume = $\frac{1}{2}hran[1 + (a'/a) + (a'/a)^2].$

Lateral area = slant height \times half sum of perimeters of bases = alant height \times perimeter of mid-section = $\frac{1}{2}sn(r+r')$. Here r,r' = radii

of inscribed circles; $s = \sqrt{(r - r')^2 + h^2}$; a,a' = sides of lower and upperbases; n = number of sides.

Frustum of Right Circular Cone (Fig. 73). Volume = $\frac{1}{2\pi r^2} h [1 + (r'/r) + (r'/r)^2] = \frac{1}{2\pi} h (r^2 + rr' + r'^2) = \frac{1}{2\pi} h [(r + r')^2 + \frac{1}{2\pi} (r - r')^2]$. Lateral area = $\pi s(r + r')$; $s = \sqrt{(r - r')^2 + h^2}$.

Any Pyramid or Cone. Volume = $\frac{1}{2}Bh$. B = area of base; h = perpendicular distance from vertex to plane in which base lies.

Any Pyramidal or Conical Frustum (Fig. 74). $\frac{1}{2}h(B + \sqrt{BB'} + B') = \frac{1}{2}hB[1 + (P'/P) + (P'/P)^2].$ Here B, B' = areas of lower and upper bases; P, P' = perimeters of lower and upper bases.

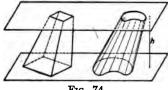

Fig. 74.

Fig. 75.

Fig. 76.

Obelisk (Frustum of a rectangular pyramid. Fig. 75). Volume = $\frac{1}{2}h[(2a+a_1)b+(2a_1+a)b_1] = \frac{1}{2}h[ab+(a+a_1)(b+b_1)+a_1b_1].$

Wedge (Rectangular base; a_1 parallel to a,a and at distance h above base. Fig. 76). Volume = $\frac{1}{2}hb(2a+a_1)$.

Sphere. Volume = $V = \frac{1}{2}\pi r^3 = 4.188790r^3 = \frac{1}{2}\pi d^3 = 0.523599d^3$ (table, p. 36) = 36 volume of circumscribed cylinder. Area = $A = 4\pi r^2$ = four great circles (table, p. 30) = $\pi d^2 = 3.14159d^2 =$ lateral area of circumscribed cylinder. Here r = radius; $d = 2r = \text{diameter} = \sqrt[3]{6V/\pi} = 1.24070 \sqrt[3]{V} = \sqrt{A/\pi} = 1.24070 \sqrt[3]{V} = \sqrt{A/\pi}$ $0.56419\sqrt{A}$

Hollow Sphere, or spherical shell. Volume = $\frac{4}{3}\pi(R^3-r^3)=\frac{1}{3}\pi(D^3-d^3)=4\pi R_1^2t+\frac{1}{3}\pi t^3.$ R,r = outer and inner radii; D,d = outer and inner diameters; t = thickness = R - r; $R_1 = \text{mean radius} =$ $\frac{1}{2}(R+r)$.

Spherical Segment of One Base. Zone (spherical "cap" of Fig. 78). Volume = $\frac{1}{4\pi}h(3a^2 + h^2) = \frac{1}{4\pi}h^2(3r - h)$ (table, p. 38). Lateral area (of zone) = $2\pi rh = \pi(a^2 + h^2)$. Note: $a^2 = h(2r - h)$, where r = radius of sphere.

Any Spherical Segment. Zone (Fig. 77). Volume = $\frac{1}{24\pi}h(3a^2 + 3a_1^2 + h^2)$. Lateral area (zone) = $2\pi\tau h$. Here τ = radius of sphere. If the inscribed frustum of a cone be removed from the spherical segment, the volume remaining is $\frac{1}{2}6\pi hc^2$, where c = slantheight of frustum = $\sqrt{h^2 + (a - a_1)^2}$.

Fig. 77.

Fig. 78.

Spherical Sector (Fig. 78). Volume = $1/3r \times \text{area}$ of cap = $3/3\pi r^2 h$. Total area = area of cap + area of cone = $2\pi rh + \pi ra$. Note: a^2 = h(2r-h).

Spherical Wedge bounded by two plane semicircles and a lune. (Fig. 79.) Volume of wedge \div volume of sphere = $u/360^{\circ}$. Area of lune \div area of sphere = $u/360^{\circ}$. u = dihedral angle of the wedge.

Spherical Triangle bounded by arcs of three great circles. (Fig. 80.) Area of triangle = $\pi r^2 E/180^\circ$ = area of octant $\times E/90^\circ$. E = spherical excess = 180° – (A + B + C), where A, B, and C are angles of the triangle. See also p. 134.

Solid Angles. Any portion of a spherical surface subtends what is called a solid angle at the center of the sphere. If the area of the given

portion of spherical surface is equal to the square of the radius, the subtended solid angle is called a **steradian**, and this is commonly taken as the unit. The entire solid angle about the center is called a **steregon**, so that 4π steradians = 1 steregon. A so-called "solid right angle" is the solid angle subtended by a quadrantal (or trirectangular) spherical triangle, and a "spherical degree" (now little used) is a solid angle equal to $\frac{1}{100}$ of a solid right angle. Hence 720 spherical degrees = 1 steregon, or π steradians = 180 spherical degrees. If u = the angle

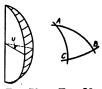

Fig. 79. Fig. 80.

which an element of a cone makes with its axis, then the solid angle of the cone contains $2\pi(1 - \cos u)$ steradians.

Regular Polyhedra. A = area of surface; V = volume; a = edge.

Name of solid (see p. 100)	Bounded by	A/a^2	V/a^s
Tetrahedron	4 triangles	1.7321	0.1179
Cube	6 squares	6.0000	1.0000
Octahedron	8 triangles	3.4641	0.4714
Dodecahedron	12 pentagons	20.6457	7.6631
Icosahedron	20 triangles	8.6603	2.1817

Ellipsoid (Fig. 81). Volume = $\frac{1}{2}\pi abc$, where a, b, c = semi-axes.

Spheroid (or ellipsoid of revolution). The volume of any segment made by two planes perpendicular to the axis of revolution may be found accurately by the prismoidal formula (p. 111).

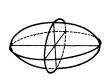

Fig. 81.

Fig. 82.

Fig. 83.

Fig. 84.

Paraboloid of Revolution (Fig. 82). Volume = $\frac{1}{2}\pi r^2h = \frac{1}{2}$ volume of circumscribed cylinder.

Segment of Paraboloid of Revolution (Bases perpendicular to axis, Fig. 83). Volume of segment = $\frac{1}{2}\pi(R^2 + r^2)h$.

Barrels or Casks (Fig. 84). Volume = $\Re_2\pi h(2D^2+d^2)$ approx. for circular staves. Volume = $\Re_5\pi h(2D^2+Dd+3d^2)$ exactly for parabolic staves.

For a standing cask, partially full, compute contents by the prismoidal formula, p. 111. Roughly, the number of gallons, G, in a cask is given by $G = 0.0034n^2h$, where n = number of inches in the mean diameter, or 1/2(D+d), and h= number of inches in the height.

Volume = Torus, or Anchor Ring (Fig. 85). $2\pi^2 cr^2$. Area = $4\pi^2 cr$ (Proof by theorems of Pappus).

Fig. 85.

Theorems of Pappus. 1. Assume that a plane figure, area A, revolves about an axis in its plane but not cutting it; and let s = length of circular arc traced by its center of gravity. Then volume of the solid generated by A is V = As. For a complete revolution, $V = 2\pi rA$, where r = distancefrom axis to center of gravity of A.

2. Assume that a plane curve, length l, revolves about an axis in its plane but not cutting it; and let s = length of circular arc traced by its center of gravity. Then area of the surface generated by l is S = ls. For a complete revolution, $S = 2\pi r l$, where r = distance from axis to center of gravity of l.

NOTE. If V_1 or S_1 about any axis is known, then V_2 or S_2 about any parallel axis can be readily computed when the distance between the axes is known.

Generalized Theorems of Pappus. Consider any curved path of length s. If (1) a plane figure, area A [or (2) a plane curve, length l moves so that its center of gravity slides along this curved path (Fig. 86), while the plane of A [or l] remains always perpendicular to the path, then (1) the volume generated by A is V = Asand (2) the area generated by l is S = ls. The

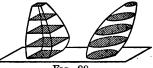

path is assumed to curve so gradually that successive positions of A [or l] will not intersect.

The Prismoidal Formula (Fig. 87). Volume = $\frac{1}{2}h(A + B + 4M)$, where h =altitude, A and B =areas of bases and M =area of a plane section

midway between the bases. This formula is exactly true for any solid lying between two parallel planes and such that the area of a section at distance x from one of these planes is

expressible as a polynomial of tot higher than the third degree in x. approximately true for many other solids.

Simpson's Rule may be applied to finding volumes, if the ordinates y_1, y_2 , be interpreted as the areas of plane sections, at constant distance h apart (p. 106).

Cavalieri's Theorem. Assume two solids to have their bases in the same plane. If the plane section of one solid at every distance x above the base is equal in area to the plane section of the other solid at the same distance x above the base, then the volumes of the two solids will be equal. See Fig. 88.

ALGEBRA

FORMAL ALGEBRA

Notation. The main points of separation in a simple algebraic expression are the + and - signs. Thus, $a + b \times c - d + x + y$ is to be interpreted as $a + (b \times c) - (d \div x) + y$. In other words, the range of operation of the symbols \times and + extends only so far as the next + or - sign. As between the signs \times and \div themselves, $a \div b \times c$ means, properly speaking, $a \div (b \times c)$; that is, the \div sign is the stronger separative; but this rule is not always strictly followed, and in order to avoid ambiguity it is better to use the parentheses.

The range of influence of exponents and radical signs extends only over the next adjacent quantity. Thus, $2ax^3$ means $2a(x^3)$, and $\sqrt{2ax}$ means $(\sqrt{2})$ (ax). Instead of $\sqrt{2}ax$, it is safer, however, to write $\sqrt{2}ax$, or, better, $ax\sqrt{2}$.

Any expression within parentheses is to be treated as a single quantity. A horizontal bar serves the same purpose as parentheses.

The notation $a \cdot b$, or simply ab, means $a \times b$; and a : b, or a/b, means a + b. The symbol |a| means the "absolute value of a," regardless of sign; thus, |-2| = |+2| = 2.

The symbol n! (where n is a whole number) is read: "n factorial," and means the product of the natural numbers from 1 to n, inclusive. 1! = 1; $2! = 1 \times 2$; $3! = 1 \times 2 \times 3$; $4! = 1 \times 2 \times 3 \times 4$; etc.

The symbol ≠ or + means "not equal to"; ± means "plus or minus." The symbol ≈ is sometimes used for "approximately equal to."

Addition and Subtraction.
$$a + b = b + a$$
.

$$(a + b) + c = a + (b + c)$$
. $a - (-b) = a + b$. $a - a = 0$.

a + (x - y + z) = a + x - y + z, a - (x - y + z) = a - x + y - s. A minus sign preceding a parenthesis operates to reverse the sign of every term within, when the parentheses are removed.

Multiplication and Simple Factoring. ab = ba. (ab)c = a(bc). a(b+c) = ab + ac. a(b-c) = ab - ac. Also, $a \times (-b) = -ab$, and $(-a) \times (-b) = ab$; "unlike signs give minus; like signs give plus."

$$(a + b)(a - b) = a^2 - b^2$$
.

$$(a+b)^2 = a^2 + 2ab + b^2$$
, $(a-b)^3 = a^3 - 2ab + b^3$.
 $(a+b)^3 = a^3 + 3a^2b + 3ab^2 + b^3$, $(a-b)^3 = a^3 - 3a^2b + 3ab^3 - b^3$; etc.
(See table of binomial coefficients, p. 39; also p. 114.)

$$a^2 - b^2 = (a - b)(a + b),$$
 $a^3 - b^3 = (a - b)(a^2 + ab + b^3).$ $a^n - b^n = (a - b)(a^{n-1} + a^{n-2}b + a^{n-3}b^2 + ... + ab^{n-2} + b^{n-1}).$

$$a^n + b^n$$
 is factorable by $a + b$ only when n is odd; thus,

$$a^3 + b^3 = (a + b)(a^2 - ab + b^2),$$

$$a^5 + b^5 = (a + b)(a^4 - a^3b + a^2b^2 - ab^3 + b^4)$$
; etc.

The following transformation is sometimes useful:

$$ax^{2}+bx+c=a\left[\left(x+\frac{b}{2a}\right)^{2}-\left(\frac{\sqrt{b^{2}-4ac}}{2a}\right)^{2}\right].$$

Fractions. If m is not zero, $\frac{ma + mb + mc}{mx + my} = \frac{a + b + c}{x + y}$; that is, both numerator and denominator of a fraction may be multiplied or divided by any quantity different from zero, without altering the value of the fraction.

To add two fractions, reduce each to a common denominator, and add the numerators: $\frac{a}{b} + \frac{x}{y} = \frac{ay}{by} + \frac{bx}{by} = \frac{ay + bx}{by}$.

To multiply two fractions:
$$\frac{a}{b} \times \frac{x}{y} = \frac{ax}{by}$$
; $\frac{a}{b} \times x = \frac{a}{b} \times \frac{x}{1} = \frac{ax}{b}$.

To divide one fraction by another, invert the divisor and multiply:

$$\frac{a}{b} \div \frac{x}{y} = \frac{a}{b} \times \frac{y}{x} = \frac{ay}{bx}; \quad \frac{a}{b} \div x = \frac{a}{b} \times \frac{1}{x} = \frac{a}{bx}.$$

Eatio and Proportion. The notation a:b::c:d, which is now passing out of use, is read: "a is to b as c is to d," and means simply (a/b) = (c/d), or ad = bc. a and d are called the "extremes," b and c the "means," and d the "fourth proportional" to a, b, and c. The "mean proportional" between two numbers is the square root of their product; also called the "geometric mean" of the numbers (p. 115). If a/b = c/d, then (a + b)/b = (c + d)/d, and (a - b)/b = (c - d)/d; whence also, (a + b)/(a - b) = (c + d)/(c - d). If a/x = b/y = c/z = ... = r, then

$$(a+b+c+...)/(x+y+z+...) = r.$$

Variation. The notation $x \propto y$ is read: "x varies directly as y," or "x is directly proportional to y," and means x = ky, where k is some constant. To determine the constant k, it is sufficient to know any pair of values, as x_1 and y_1 , which belong together; then $x_1 = ky_1$, and hence $x/x_1 = y/y_1$, or $x = (x_1/y_1)y$. The expression "x varies inversely as y," or "x is inversely proportional to y," means that x is proportional to 1/y, or x = k/y.

Exponents. $a^{m+n} = a^m a^n$. $a^{m-n} = a^m/a^n$. $a^0 = 1$ (if $a \neq 0$). $a^{-m} = 1/a^m$. $(a^m)^n = a^{mn}$. $a^{1/n} = \sqrt[n]{a}$. Thus: $a^{\frac{1}{2}} = \sqrt[n]{a}$, and $a^{\frac{1}{2}} = \sqrt[n]{a}$. $a^{m/n} = \sqrt[n]{a^m}$. Thus: $a^{\frac{2}{3}} = \sqrt[n]{a}$ and $a^{\frac{3}{2}} = \sqrt[n]{a}$. $(\sqrt[n]{a})^n = a$. $(ab)^n = a^n b^n$. $(a/b)^n = a^n/b^n$. $(-a)^n = a^n$ if n is even. $(-a)^n = -a^n$ if n is positive and increases indefinitely, a^n becomes infinite if a > 1, and approaches 0 if a < 1 (a being always positive). Graphs, p. 174; series, p. 160.

Eadicals. Except in the simple cases of square root and cube root, radical signs should always be replaced by fractional exponents: $\sqrt[n]{a} = a^{1/n}$. $(\sqrt{a})^n = (a^{1/n})^n = a$. If n is odd, $\sqrt[n]{-a} = -\sqrt[n]{a}$; but if n is even, $\sqrt[n]{-a}$ is imaginary. Every positive number a has two square roots, one positive and the other negative; but the notation \sqrt{a} always means the positive root; thus, $\sqrt{9} = 3$; $-\sqrt{9} = -3$. If the denominator of a fraction is of the form $\sqrt{a} \pm \sqrt{b}$, it is possible to "rationalize the denominator" by multiplying both numerator and denominator by $\sqrt{a} \mp \sqrt{b}$. Thus:

$$\frac{\sqrt{a} + \sqrt{b}}{\sqrt{a} - \sqrt{b}} = \frac{(\sqrt{a} + \sqrt{b})(\sqrt{a} + \sqrt{b})}{(\sqrt{a} - \sqrt{b})(\sqrt{a} + \sqrt{b})} = \frac{a + b + 2\sqrt{ab}}{a - b}$$

Logarithms. (For the use of logarithms in numerical computation, see p. 91.) The logarithm of a (positive) number N is the exponent of that power to which the base (10 or e) must be raised to produce N. Thus, $x = \log_{10} N$ means that $10^x = N$, and $x = \log_{10} N$ means that $e^x = N$. Logarithms to base 10 are called **common**, denary, or Briggsian logarithms. For table of 4-place common logarithms see pp. 40-43.

114 ALGEBRA

Logarithms to base e are called **hyperbolic**, **natural**, or **Napierian** logarithms. Here $e = 1 + 1 + 1/2! + 1/3! + 1/4! + \dots = 2.718281828459...$ For table of 4-place hyperbolic logarithms see pp. 58, 59.

If the subscript 10 or e is omitted, the base must be inferred from the context, the base 10 being used in numerical computation, and the base e in theoretical work. In either system,

$$\begin{array}{lll} \log \ (ab) &= \log a + \log b & \log \ (a^n) &= n \log a & \log \ 0 &= -\infty \\ \log \ (a/b) &= \log a - \log b & \log \ (\sqrt[n]{a}) &= (1/n) \log a & \log \ 1 &= 0 \\ \log \ (1/n) &= -\log n & \log \ (\text{base}) &= 1 & \log \infty &= \infty \end{array}$$

The two systems are related as follows:

 $\log_{10}e = M = 0.4342944819 \dots$; $\log_{1}0 = 1/M = 2.3025850930 \dots$ $\log_{10}x = 0.4343 \log_{0}x$; $\log_{0}x = 2.3026 \log_{10}x$.

For tables of multiples of M and 1/M, see p. 62. For graphs of the logarithmic and exponential functions, see p. 174; series, p. 160.

The Binomial Theorem. (For table of binomial coefficients, see p. 39 and p. 116.)

Let
$$(n)_1 = n$$
, $(n)_2 = \frac{n(n-1)}{1 \times 2}$, $(n)_3 = \frac{n(n-1)(n-2)}{1 \times 2 \times 3}$,
 $(n)_4 = \frac{n(n-1)(n-2)(n-3)}{1 \times 2 \times 3 \times 4}$, . . .

Then, for any value of n, provided |x| < 1,

$$(1+x)^n = 1 + (n)_1x + (n)_2x^2 + (n)_3x^3 + (n)_4x^4 + \dots$$

(If n is a positive integer, the series breaks off with the term in x^n , and is valid without restrictions on x, see p. 112.)

The most useful special cases are the following:

$$\sqrt{1+x} = (1+x)^{\frac{1}{2}} = 1 + \frac{1}{2}x - \frac{1}{8}x^{2} + \frac{1}{16}x^{3} - \frac{5}{128}x^{4} + \dots (|x| < 1)$$

$$\sqrt[3]{1+x} = (1+x)^{\frac{1}{3}} = 1 + \frac{1}{3}x - \frac{1}{9}x^{2} + \frac{5}{81}x^{3} - \frac{10}{243}x^{4} + \dots (|x| < 1)$$

$$\frac{1}{1+x} = (1+x)^{-1} = 1 - x + x^{2} - x^{3} + x^{4} - \dots (|x| < 1)$$

$$\frac{1}{\sqrt{1+x}} = (1+x)^{-\frac{1}{2}} = 1 - \frac{1}{2}x + \frac{3}{8}x^2 - \frac{5}{16}x^3 + \frac{35}{128}x^4 - \dots (|x| < 1)$$

$$\frac{1}{\sqrt[3]{1+x}} = (1+x)^{-\frac{1}{3}} = 1 - \frac{1}{3}x + \frac{2}{9}x^2 - \frac{14}{81}x^3 + \frac{35}{243}x^4 - \dots (|x| < 1)$$

$$\sqrt{(1+x)^3} = (1+x)^{\frac{3}{2}} = 1 + \frac{3}{2}x + \frac{3}{8}x^2 - \frac{1}{16}x^3 + \frac{3}{128}x^4 - \dots (|x| < 1)$$

$$\frac{1}{\sqrt{(1+x)^3}} = (1+x)^{-\frac{3}{2}} = 1 - \frac{3}{2}x + \frac{15}{8}x^2 - \frac{35}{16}x^3 + \frac{315}{128}x^4 - \dots (|x| < 1)$$

with corresponding formulæ for $\sqrt{1-x}$, etc., obtained by reversing the signs of the odd powers of x. Also, provided |b| < |a|:

$$(a+b)^n = a^n \left(1 + \frac{b}{a}\right)^n = a^n + (n)_1 a^{n-1}b + (n)_2 a^{n-2}b^2 + (n)_3 a^{n-3}b^3 + \dots$$

where $(n)_1$, $(n)_2$, etc., have the values given above.

Arithmetical Progression. In an arithmetical progression, a; a + d; a + 2d; a + 3d; . . ., each term is obtained from the preceding term by adding a constant, called the constant difference, d. If n is the number of terms, the last term is l = a + (n - 1)d; the "average" term is $\mathcal{H}(a + b)$;

and the sum of the *n* terms is *n* times the average term, or $S = \frac{1}{2}n(a+l)$. The arithmetical mean between *a* and *b* is (a+b)/2.

Geometrical Progression. In a geometrical progression, a; ar; ar^3 ; ar^3 ; . . ., each term is obtained from the preceding term by multiplying by a constant, called the constant ratio, r. The nth term is ar^{n-1} . The sum of the first n terms is $S = a(r^n - 1)/(r - 1) = a(1 - r^n)/(1 - r)$. If r is a positive or negative fraction, that is, if -1 < r < +1, then r^n will approach zero as n increases, and the sum of n terms will approach a/(1 - r) as a limit. The **geometric mean** between a and b is \sqrt{ab} ; also called the **mean proportional** between a and b (p. 113; construction, p. 102).

The harmonic mean between a and b is 2ab/(a+b).

Summation of Certain Series by Second and Third Differences.

Let $a_1, a_2, a_3, \ldots a_n$ be any series of n numbers, as in the first column of the adjoining scheme. By subtracting each number from the next following, form the column of "first differences," and by repeating this process, form the columns of second, third, etc., differences. If the kth differences are all equal, so that subsequent differences are all zero, the original series is called an arithmetical series of the kth order. In this special case the -8 7 -12 6 series can be summed as follows: Denote the numbers -1 1 -6 6 which stand at the head of the successive columns of differences by D', D'', D''', . . . Then the nth term of the series is a_n , and the sum of the first n terms is S_n , where

$$a_{n} = a_{1} + (n-1)D' + \frac{(n-1)(n-2)}{1 \times 2}D'' + \frac{(n-1)(n-2)(n-3)}{1 \times 2 \times 3}D''' + \cdots$$

$$S_{n} = na_{1} + \frac{n(n-1)}{1 \times 2}D' + \frac{n(n-1)(n-2)}{1 \times 2 \times 3}D'' + \frac{n(n-1)(n-2)(n-3)}{1 \times 2 \times 3 \times 4}D''' + \cdots$$

If the series is, for example, of the third order, each of these formulæ will stop with the term involving D'''; and only a few terms of the series are required for the computation of the D's. (Differentials, p. 159.)

Sum of the Squares or Cubes of the First n Natural Numbers.

$$\begin{array}{l} 1+2+3+\ldots +(n-1)+n=\frac{1}{2}n(n+1).\\ 1^2+2^3+3^2+\ldots +(n-1)^2+n^2=\frac{1}{2}n(n+1)(2n+1).\\ 1^3+2^3+3^3+\ldots +(n-1)^3+n^3=[\frac{1}{2}n(n+1)]^2. \end{array}$$

Formula for Interpolation by Second Differences. In any ordinary table giving a quantity y as a function of a variable x, let it be required to find the value of y corresponding to a value of x which is not given directly in the table, but which lies between two tabulated values, as x_1 and x_2 . If $x = x_1 + md$, where $d = x_2 - x_1 =$ the constant interval between two successive x's, and m is some proper fraction, then the corresponding value of y will be given by the formula

$$y = y_1 + mD' + \frac{m(m-1)}{1 \times 2}D'' + \frac{m(m-1)(m-2)}{1 \times 2 \times 3}D''' + \dots$$

where D', D'', D''', . . . are the first, second, third, . . . differences in the

116 ALGEBRA

series of y's which begins with y_1 (see above), provided the function is of such a nature that the differences of higher orders become negligibly small. The coefficients of D', D'', D''', . . . in the formula are the binomial coefficients for fractional values of m (see following table). The several terms of the formula (with careful attention to sign) are the successive corrections which must be added to y_1 ; the sum of these corrections should be rounded out to the nearest unit of the last significant place before adding. If D' < 4, the term involving D'', and later terms, can be neglected; the formula then reduces to $y = y_1 + mD'$, which is the familiar formula for ordinary, or "linear," interpolation. If D''' < 8 (or D''''' < 12, or D''''' < 16), the term involving D''' (or D''''', or D'''''') can be neglected.

Binomial Coefficients for Fractional Values of m

m	(m) ₂	(m) ₃	(m) ₄	(m)g
0.0	- 0,0000	0.0000	- 0,0000	0.0000
0.1	- 0.0450	0.0285	- 0.0207 l	0.0161
0.2	0.0800	0.0480	- 0.0336	0.0255
0.3	- 0.1050	0.0595	- 0.0402	0.0297
0.4	- 0.1200	0.0640	- 0.0416	0.0300
0.5	- 0.1250	0.0625	- 0.0391	0.0273
0.6	- 0.1200	0.0560	- 0.0336	0.0228
0.7	- 0.1050	0.0455	- 0.0262	0.0173
0.8	- 0.0800	0.0320	- 0.0176	0.0113
0.9	- 0.0450	0.0165	- 0.0087	0.0054

Here
$$(m)_2 = \frac{m(m-1)}{1 \times 2}$$
, $(m)_3 = \frac{m(m-1)(m-2)}{1 \times 2 \times 3}$, $(m)_4 = \frac{m(m-1)(m-2)(m-3)}{1 \times 2 \times 3 \times 4}$, etc.

Compare p. 39.

Permutations. The number of possible permutations or arrangements of n different elements is $1 \times 2 \times 3 \times \ldots \times n = n!$ (read: "n factorial"). If among the n elements there are p equal ones of one sort, q equal ones of another sort, r equal ones of a third sort, etc., then the number of possible permutations is $(n!)/(p! \times q! \times r! \times \ldots)$, where $p+q+r+\ldots=n$.

Combinations. The number of possible combinations or groups of n elements taken r at a time (without repetition of any element within any one group), is $[n(n-1)(n-2)(n-3) \dots (n-r+1)]/(r!) = (n)_r$. (See table of binomial coefficients, p. 39.) If repetitions are allowed, so that a group, for example, may contain as many as r equal elements, then the number of combinations of n elements taken r at a time is $(m)_r$, where m = n + r - 1. Note: $(n)_1 + (n)_2 + \dots + (n)_n = 2^n - 1$.

SOLUTION OF EQUATIONS IN ONE UNKNOWN QUANTITY

Roots of an Equation. An equation containing a single variable x will in general be true for some values of x and false for other values. Any value of x for which the equation is true is called a **root** of the equation. To "solve" an equation means to find all its roots. Any root of an equation, when substituted therein for x, will "satisfy" the equation. An equation which is true for all values of x, like $(x+1)^2 = x^2 + 2x + 1$, is called an **identity** [often written $(x+1)^2 \equiv x^2 + 2x + 1$].

Types of Equations.

(a) Algebraic Equations:

of the first degree (linear), e.g., 2x + 6 = 0 (root: x = -3);

of the second degree (quadratic), e.g., $x^2 - 2x - 3 = 0$ (roots: -1, 3); of the third degree (cubic), e.g., $x^2 - 6x^2 + 5x + 12 = 0$ (roots: -1, 3, 4).

(b) Transcendental Equations:

exponential equations, e.g., $2^x = 32$ (root: x = 5); $2^x = -32$ (no root); trigonometric equations, e.g., $10 \sin x - \sin 3x = 4$ (roots: 30°, 150°).

Legitimate Operations on Equations. An equation which is true for a particular value of x will remain true for that value of x after any one of the following operations is performed:

Adding any quantity to both sides; subtracting any quantity from both sides; transposing any term from one side to the other, provided its sign be changed; multiplying or dividing both sides by any quantity which is not zero; changing the signs of all the terms; raising both sides to any positive integral power; extracting any odd root of both sides; extracting any even root of both sides, provided the ± sign is used; taking the logarithms of both sides (both sides being positive); taking the sin, cos, tan, etc., of both

Notice, however, that the new equation obtained by some of these operations may possess "additional roots" which did not belong to the original equation. This occurs especially when both sides are squared; thus, x = -2 has only one root, namely, -2; but $x^2 = 4$, obtained by squaring, has not only the root -2 but also another root, +2.

Equations of the First Degree (Linear Equations). Solution: Collect all the terms involving x on one side of the equation, thus: ax = b, where **a** and b are known numbers. Then divide through by the coefficient of x, obtaining x = b/a as the root.

Equations of the Second Degree (Quadratic Equations). Solution: Throw the equation into the standard form $ax^2 + bx + c = 0$. Then the two roots are:

$$x_1 = \frac{-b + \sqrt{b^2 - 4ac}}{2a} \qquad x_2 = \frac{-b - \sqrt{b^2 - 4ac}}{2a}$$

The roots are real-and-distinct, coincident, or imaginary, according as $b^2 - 4ac$ is positive, zero, or negative. The sum of the roots is $x_1 + x_2$ = -b/a; the product of the roots is $x_1x_2 = c/a$.

GRAPHICAL SOLUTION. Write the equation in the form $x^2 = px + q$, and plot the parabola $y_1 = x^2$, and the straight line $y_2 = px + q$. The abscisse of the points of intersection will be the roots of the equation. If the line does not cut the parabola, the roots are imaginary.

Equations of the Third Degree with Term in x2 Absent. Solution: After dividing through by the coefficient of x^3 , any equation of this type can be written $x^2 = Ax + B$. Let p = A/3 and q = B/2. The general solution is as follows:

Case 1.
$$q^2 - p^2$$
 positive. One root is real, namely $x_1 = \sqrt[3]{q + \sqrt{q^2 - p^2}} + \sqrt[3]{q - \sqrt{q^2 - p^2}}$; the other two roots are imaginary.

Case 2. $q^2 - p^3 = zero$. Three roots real, but two of them equal.

$$x_1 = 2 \sqrt[3]{q}, \ x_2 = -\sqrt[3]{q}, \ x_3 = -\sqrt[3]{q}.$$

 $x_1=2\sqrt[3]{q},\ x_2=-\sqrt[3]{q},\ x_3=-\sqrt[3]{q}.$ Case 3. q^2-p^3 negative. All three roots real and distinct. Determine an angle u between 0 and 180°, such that $\cos u = q/(p\sqrt{p})$. Then $x_1 = 2\sqrt{p}\cos(u/3), x_2 = 2\sqrt{p}\cos(u/3 + 120^\circ), x_3 = 2\sqrt{p}\cos(u/3 + 240^\circ).$

GRAPHICAL SOLUTION. Plot the curve $y_1 = x^2$, and the straight line $y_2 = Ax + B$. The abscisse of the points of intersection will be the roots of the equation.

Equations of the Third Degree (General Case). Solution: The general cubic equation, after dividing through by the coefficient of the highest 118 ALGEBRA

power, may be written $x^3 + ax^2 + bx + c = 0$. To get rid of the term in x^2 , let $x = x_1 - a/3$. The equation then becomes $x_1^2 = Ax_1 + B$, where $A = 3(a/3)^2 - b$, and $B = -2(a/3)^3 + b(a/3) - c$. Solve this equation for x_1 , by the method above, and then find x itself from $x = x_1 - (a/3)$.

Graphical Solution. Without getting rid of the term in x^2 , write the equation in the form $x^2 = -a[x + (b/2a)]^2 + [a(b/2a)^2 - c]$, and solve by the graphical method.

General Properties of Algebraic Equations. An algebraic equation of the nth degree in x is an equation of the type

$$a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_{n-1}x + a_n = 0$$

where the a's are any given numbers (a_0 not zero), the expression on the left being called a **polynomial** of the nth degree in x. Such an equation will, in general, have n roots; but some of these n roots may be equal, and some may be imaginary. **Imaginary roots** always occur in pairs.

If the equation is written in the form: (a polynomial in x) = 0, then (1) if a is a root of the equation, x - a is a factor of the polynomial; (2) if the polynomial can be factored in the form (x - p)(x - q)(x - r). . . = 0, each of the quantities p, q, r, . . . is a root of the equation; (3) if x is very large (either positive or negative), the higher powers of x are the most important; (4) if x is very small, the higher powers may be neglected.

Short Method of Substitution in a Polynomial. To find the value of $4x^4 - 14x^3 + 23x - 26$ when x = 3, for example, first arrange the terms in order of descending powers of x, and write the detached coefficients, with their signs, in a row, taking care to supply

a zero coefficient for any missing term, in-4 -14 0 23 -26 (3 cluding the constant term. Then, beginning at the left, bring down the first coefficient; $-\frac{12}{6}$ $-\frac{18}{5}$ 15 multiply this by 3, and add to the second 4 -2 -6 5 -11 coefficient; multiply this result by 3 again,

and add to the third coefficient; and so on. The final result, -11, is the value of the polynomial when x=3.

Short Method of Dividing a Polynomial by x - a. The device just explained gives not only the value of the polynomial when x = 3, but also the result of dividing the polynomial by x - 3. Thus, in the case illustrated, the quotient is $4x^3 - 2x^2 - 6x + 5$ and the remainder is -11. That is, $4x^4 - 14x^5 + 0x^2 + 23x - 26 = (x - 3)(4x^3 - 2x^2 - 6x + 5) - 11$.

Exponential Equations. To solve an equation of the form $a^x = b$, take the logarithms of both sides: $x \log a = \log b$, whence $x = (\log b)/(\log a)$. For example, if $3^x = 0.4$, $x = \log 0.4/\log 3 = (0.6021 - 1)/0.4771 = -0.3979/0.4771 = -0.8340$. Notice that the complete logarithm must be taken, not merely the mantissa.

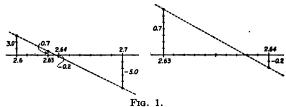

Trigonometric Equations. (1) To solve $a \cos x + b \sin x = c$, where a and b are positive: Find the acute angle u for which $\tan u = b/a$, and the angle v (between 0 and 180°) for which $\cos v = c/\sqrt{a^2 + b^2}$. Then $x_1 = u + v$ and $x_2 = u - v$ are roots of the equation.

(2) To solve $a \cos x - b \sin x = c$, where a and b are positive: Find u and v as above. Then $x_1 = -(u + v)$ and $x_2 = -(u - v)$ are roots of the equation.

General Method of Solution by Trial and Error. This method is applicable to a numerical equation of any form, and can be carried out to any desired degree of approximation. It is especially useful when a first approximation to a root is already known. Write the equation in the form

f(x) = 0, where f(x) means any function of x, and plot the curve y = f(x) for a sufficient number of values of x to obtain a general idea of the shape of the curve. Then pick out the regions in which the curve appears to cross the axis of x, and plot the curve more accurately in each of these regions. Thus, by successive approximations, plotting the important parts of the curve on a larger and larger scale, determine as accurately as necessary the points where the curve crosses the axis—that is, the values of x which make f(x) equal to zero.

Thus, suppose that f(x) = 3.0 when x = 2.6 and -5.0 when x = 2.7 (see Fig. 1). Then the curve must cross the axis somewhere between x = 2.6 and x = 2.7; and since it will not vary greatly from a straight line between those points, it is seen that it must

cross near 2.64. Suppose the value of f(x) when computed for x = 2.64, is -0.2, and when computed for x = 2.63 is +0.7; then the root lies between x = 2.63 and 2.64. Plotting this section on the larger scale, it is seen that the next guess should be about 2.638; and so on.

Instead of writing the original equation with all the terms on the left-hand side, it is often better to divide the expression into two parts, say $f_1(x)$ and $f_2(x)$, writing the equation in the form $f_1(x) = f_2(x)$. If then the two curves $y_1 = f_1(x)$ and $y_2 = f_2(x)$ be plotted separately, on the same diagram, the value of x corresponding to their point of intersection will be the desired root.

SOLUTION OF SIMULTANEOUS EQUATIONS

The Meaning of a System of Simultaneous Equations. To solve a system of n simultaneous equations in n unknowns, means to find all the sets of values of the unknowns (if any) which, when substituted in the given equations, will satisfy all the equations at the same time. If a system of equations has no solution, the equations are "inconsistent;" if it has an infinite number of solutions, the equations are "not all independent."

Simultaneous Equations of the First Degree in Two Unknowns.

Factors

Here (1) is multiplied by b_2 , (2) by $-b_1$, and the products added so as to eliminate y; again, (1) is multiplied by $-a_2$, (2) by a_1 , and the products added so as to eliminate x. (The process is most conveniently performed as follows: Write the multipliers, as b_2 and $-b_1$, at the right of the equations; multiply the first term of each equation by its proper multiplier and add; then multiply the second term of each equation by its proper multiplier, and add; and so on. This is simpler than the common practice of multiplying out each equation separately before adding.) If $a_1b_2 - a_2b_1 = 0$, the equations have no solution when $c_1 \neq c_2$, and an infinite number of solutions when

120 ALGEBRA

 $c_1 = c_2$. The following special solution is possible when the sum and difference of the two unknowns are given:

Let
$$x + y = m$$
 (1)
and $x - y = n$ (2)
(1) + (2): $2x = m + n$ $\therefore x = \frac{1}{2}(m + n)$
(1) - (2): $2y = m - n$ $\therefore y = \frac{1}{2}(m - n)$

Simultaneous Equations of the Second Degree in Two Unknowns.

(a) When the product of the unknowns, and their sum or difference, are given:

(b) When the product and the sum of the squares are given:

$$xy = 5 (1) \sqrt{(4)} : x + y = 6 \text{ or } 6 \text{ or } -6 \text{ or } -6$$

$$x^{2} + y^{2} = 26 (2) \sqrt{(5)} : x - y = 4 \text{ or } -4 \text{ or } -4$$
From (1),
$$2xy = 10 (3) \qquad \therefore x = 5 \text{ or } 1 \text{ or } -1 \text{ or } -5$$

$$(2) + (3) : x^{2} + 2xy + y^{2} = 36 (4) \qquad \therefore y = 1 \text{ or } -5 \text{ or } -1$$

$$(2) - (3) : x^{2} - 2xy + y^{2} = 16 (5)$$

(c) When the sum or difference, and the sum of the squares, are given:

Then proceed as in case (a), above. Then proceed as in case (a), above.

(d) When one equation is of the first degree and the other of the second, as ax + by = c, and $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$: Solve the first equation for y in terms of x, and substitute in the second. This will give a quadratic equation in x. Solve this quadratic for the two values of x, and for each of these values of x find the corresponding value of y by substituting in the equation of the first degree.

Simultaneous Equations of the First Degree in n Unknowns. For example:

(j)
$$595x = 595;$$
 $\therefore x = 1;$ $5y = 65 - 55x = 65 - 55 = 10;$ $\therefore y = 2;$ $19z = 12 + 19x + 13y = 12 + 19 + 26 = 57;$ $\therefore z = 3;$ $2w = 3 - 4x - 3y + 5z = 3 - 4 - 6 + 15 = 8;$ $\therefore w = 4.$

Here w is eliminated from (a) and (b), obtaining (e); from (a) and (c), obtaining (f); and from (a) and (d), obtaining (g). Then z is eliminated from (e) and (f), obtaining (h), and from (e) and (g), obtaining (f). Then g is eliminated from (h) and (f), obtaining (f), which contains only the single variable x. Hence x = 1. Now substituting this value of x in either (h) or (f), g is found; substituting these values of x and g in either (e), (f), or (g), g is found; and so on. (Solution by determinants, see p. 123.)

Approximate Solution of a Set of Simultaneous Equations of the First Degree When the Number of Equations is Greater Than the Number of Unknowns. (Method of Least Squares.)

Case 1. Single Unknown Quantity. Given n equations in one unknown x; for example, n equally careful, independent measurements of some physical quantity:

$$x = x_1, x = x_2, \ldots x = x_n.$$

As the "best" value of x, take the arithmetic mean, x_0 , of the several determinations, namely, $x_0 = (x_1 + x_2 + \ldots + x_n)/n$. The quantities $v_1 = x_0 - x_1$, $v_2 = x_0 - x_2$, ... $v_n = x_0 - x_n$ are called the **residuals** of the observed values with respect to x_0 , and their absolute values (that is, their numerical values without regard to sign) are denoted by $|v_1|$, $|v_2|$, ... $|v_n|$. [It can be shown that the sum of the squares of the residuals with respect to x_0 is smaller than the sum of the squares of the residuals with respect to any other value x'_0 ; hence the name of the method: "least squares."]

The quantities r and r_0 , defined exactly by Bessel's formulæ:

$$r = \frac{0.6745}{\sqrt{n-1}} \sqrt{v_{1}^{2} + v_{2}^{2} + \dots + v_{n}^{2}},$$

$$r_{0} = \frac{0.6745}{\sqrt{n(n-1)}} \sqrt{v_{1}^{2} + v_{2}^{2} + \dots + v_{n}^{2}},$$

or given approximately by the simpler formulæ of Peters:

$$r = \frac{0.8453}{\sqrt{n(n-1)}} (|v_1| + |v_2| + \dots + |v_n|),$$

$$r_0 = \frac{0.8453}{n\sqrt{n-1}} (|v_1| + |v_2| + \dots + |v_n|),$$

are called the probable error of a single observation (r), and the probable error of the mean (r_0) , for the given series of observations. Note that $r_0 = r/\sqrt{n}$. For tables of the coefficients, see p. 63. This quantity r (or r_0) is best regarded as merely a conventional means of recording the relative precision of different sets of observations. If r is small, it may be inferred that most errors of the "accidental" class have been eliminated; but it should be especially noted that the smallness of r gives no information in regard to "constant" or "systematic" errors.

A statement like "x is equal to 2.36 with a probable error of 0.02," is written: $x = 2.36 \pm 0.02$, and is usually understood to mean that the true value of x, as far as can be told, is just as likely to lie inside as outside the interval from 2.34 to 2.38.

122 ALGEBRA

To test the **distribution of residuals**, arrange the residuals in order of magnitude, without regard to sign, and count the number, p, of residuals which are numerically less than some assigned value a; divide p by p, the total number of observations, and divide p by p, the probable error of a single observation. Do this for various values of p, and compare the results with the table on p. 63, which gives the standard distribution of residuals, as found from experience from a large number of different series of observations. In particular, the number of residuals numerically less than p should be about equal to the number numerically greater than p (if p is large). If any large discrepancy appears, the series of observations should be regarded as unsatisfactory.

Note. The "mean square error" sometimes met with is equal to the probable error divided by 0.6745.

Case 2. Several Unknown Quantities. Assume that there have been obtained by measurement or observation n different equations of the first

Given Equations $a_1x + b_1y + c_1z = p_1$ $a_2x + b_2y + c_2z = p_2$ $a_nx + b_ny + c_nz = p_n$

degree involving, say, three unknown quantities, x, y, z. There are then n simultaneous equations in three unknowns, and if n > 3 there will be, in general, no set of values of x, y, z which will satisfy all these n equations exactly. In such a case, the "best" set of values, x_0, y_0, z_0 , may be found by the method of least squares as follows. (The

process usually involves a large amount of labor; the use of a computing machine is advisable.)

First, arrange the n given equations in the form indicated, being careful not to modify any of them by multiplication or division. (Any of the coefficients may of course be zero.)

Next, form the three "normal equations" as follows: (1) Multiply each of the given equations by the coefficient of x in that equation, and add; the result will be the first normal equation.

Normal Equations $[aa]x_0 + [ab]y_0 + [ac]z_0 = [ap]$ $[ba]x_0 + [bb]y_0 + [bc]z_0 = [bp]$ $[ca]x_0 + [cb]y_0 + [cc]z_0 = [cp]$

(2) Multiply each of the given equations by the coefficient of y in that equation, and add; the result will be the second normal equation. (3) Similarly for the third. { Notation: $[aa] = a_1^2 + a_2^2 + \dots + a_n^2$;

 $[ab] = a_1b_1 + a_2b_2 + \dots + a_nb_n;$ $[ap] = a_1p_1 + a_2p_2 + \dots + a_np_n;$ etc. Finally, solve the three normal equations for the three unknowns in the usual way.

The quantities $v_1 = a_1x_0 + b_1y_0 + c_1z_0 - p_1$, etc., are called the **residuals** with respect to x_0, y_0, z_0 . [It can be shown that the sum of the squares of the residuals with respect to x_0, y_0, z_0 is smaller than the corresponding quantity with respect to any other set of values, x'_0, y'_0, z'_0 ; this relation is taken as the criterion for the "best" set of values of x, y, z.]

The probable error of a single observation is

$$r = \frac{0.6745}{\sqrt{n-m}} \sqrt{v_{1}^{2} + v_{2}^{2} + \dots + v_{n}^{2}}, \text{ or approximately,}$$

$$r = \frac{0.8453}{\sqrt{n(n-m)}} (|v_{1}| + |v_{2}| + \dots + |v_{n}|),$$

where m = the number of unknown quantities (here m = 3).

DETERMINANTS

Determinants are used chiefly in formulating theoretical results; they are seldom of use in numerical computation.

Evaluation of Determinants:

Of the second order:

$$\begin{vmatrix} a_1b_1 \\ a_2b_2 \end{vmatrix} = a_1b_2 - a_2b_1$$

Of the third order:

$$\begin{vmatrix} a_1b_1c_1 \\ a_2b_2c_2 \\ (a_3b_3c_3) \end{vmatrix} = a_1\begin{vmatrix} b_2c_2 \\ b_3c_3 \end{vmatrix} - a_2\begin{vmatrix} b_1c_1 \\ b_3c_3 \end{vmatrix} + a_3\begin{vmatrix} b_1c_1 \\ b_2c_2 \end{vmatrix}$$

$$= a_1(b_2c_3 - b_3c_2) - a_2(b_1c_3 - b_3c_1) + a_3(b_1c_2 - b_2c_1)$$

Of the fourth order:

$$\begin{vmatrix} a_1b_1c_1d_1 \\ a_2b_2c_2d_2 \\ a_3b_2c_3d_3 \\ a_4b_4c_3d_4 \end{vmatrix} = a_1\begin{vmatrix} b_2c_2d_2 \\ b_2c_3d_3 \\ b_4c_4d_4 \end{vmatrix} - a_2\begin{vmatrix} b_1c_1d_1 \\ b_2c_3d_2 \\ b_4c_3d_4 \end{vmatrix} + a_3\begin{vmatrix} b_1c_1d_1 \\ b_2c_3d_2 \\ b_4c_3d_4 \end{vmatrix} - a_4\begin{vmatrix} b_1c_1d_1 \\ b_2c_3d_2 \\ b_4c_3d_4 \end{vmatrix}$$

etc. In general, to evaluate a determinant of the nth order, take the elements of the first column with signs alternately plus and minus, and form the sum of the products obtained by multiplying each of these elements by its corresponding **minor**. The minor corresponding to any element a_1 is the determinant (of next lower order) obtained by striking out from the given determinant the row and column containing a_1 .

Properties of Determinants.

1. The columns may be changed to rows and the rows to columns:

$$\begin{vmatrix} a_1b_1c_1 \\ a_2b_2c_2 \\ a_2b_3c_3 \end{vmatrix} = \begin{vmatrix} a_1a_2a_3 \\ b_1b_2b_3 \\ c_1c_2c_3 \end{vmatrix}$$

- 2. Interchanging two columns changes the sign of the result.
- 3. If two columns are equal, the determinant is zero.
- 4. If the elements of one column are m times the elements of another column, the determinant is zero.
- 5. To multiply a determinant by any number m, multiply all the elements of any one column by m.

6.
$$\begin{vmatrix} a_1 + p_1 + q_1, & b_1 & c_1 \\ a_2 + p_2 + q_2, & b_2 & c_2 \\ a_3 + p_3 + q_3, & b_3 & c_3 \end{vmatrix} = \begin{vmatrix} a_1b_1c_1 \\ a_2b_2c_2 \\ a_3b_3c_3 \end{vmatrix} + \begin{vmatrix} p_1b_1c_1 \\ p_2b_2c_2 \\ p_3b_3c_3 \end{vmatrix} + \begin{vmatrix} q_1b_1c_1 \\ q_2b_2c_2 \\ q_3b_3c_3 \end{vmatrix}$$

7.
$$\begin{vmatrix} a_1b_1c_1 \\ a_2b_2c_2 \\ a_3b_3c_3 \end{vmatrix} = \begin{vmatrix} a_1 + mb_1, b_1 & c_1 \\ a_2 + mb_2, b_2 & c_2 \\ a_3 + mb_3, b_3 & c_3 \end{vmatrix}$$

Solution of Simultaneous Equations by Determinants.

If
$$a_1x + b_1y + c_1z = \mathbf{p}_1$$
 $a_2x + b_2y + c_2z = \mathbf{p}_2$ where $D = \begin{vmatrix} a_1b_1c_1 \\ a_2b_2c_2 \\ a_3b_2c_3 \end{vmatrix} \neq 0$,

then $x = D_1/D$,
 $y = D_2/D$, where $D_1 = \begin{vmatrix} \mathbf{p}_1b_1c_1 \\ \mathbf{p}_2b_2c_2 \\ \mathbf{z} = D_3/D$,
 $D_2 = \begin{vmatrix} a_1\mathbf{p}_1c_1 \\ a_2\mathbf{p}_2c_2 \\ a_3b_3c_3 \end{vmatrix} = \begin{vmatrix} a_1\mathbf{p}_1c_1 \\ a_2\mathbf{p}_2c_2 \\ a_3\mathbf{p}_3c_3 \end{vmatrix}$

Similarly for a larger (or smaller) number of equations.

THE ALGEBRA OF IMAGINARY OR COMPLEX QUANTITIES

In the algebra of imaginary or complex quantities, the objects on which the operations of the algebra are performed are not numbers in any ordinary sense of the word, but are best thought of as **points** in a plane (or as **vectors** drawn from a fixed origin to these points). The "**complex plane**" is determined by three fundamental points, O, U, i, arranged as in Fig. 2 and called the **zero point**, the **unit point**, and the **imaginary unit point**, respectively. All points on the line through O and U are called **real points**—positive if

on the right of O, negative if on the left. All theremaining points in the plane are called **imaginary points**—those on the line through O and i being called the **pure imaginary points**.

The position of any point A in the plane may be determined by the distance from the origin O, measured in terms of OU as the unit length, and the angle φ which OA makes with the positive direction of the axis of reals. The distance r is sometimes called the modulus or absolute value of the point; the angle φ is sometimes called

Fig. 2.

the amplitude or argument of the point. The notation $A = (3, \angle 120^{\circ})$ means the point whose distance, r, is 3 times OU, and whose angle, φ , is 120°. The development of the algebra depends wholly on the definitions of three fundamental operations denoted by A + B, $A \times B$, and e^A , as follows.

Addition and Subtraction. The sum, A+B, of two points A and B is defined as the point reached by starting from A and performing a journey equal in length and direction to the journey from O to B. That is, the vector

from O to A + B is the vector sum of the vectors OA and OB. In case A and B are not in line with O, the point A + B is the fourth vertex of a parallelogram of which OA and OB are the sides (Fig. 3). Conversely, if any two points A and B are given, there is a definite point X such that A = B + X; this point X is called the **remainder**, A minus B, and is denoted by A - B. The point O - B is denoted for brevity

by -B. With these definitions of A + B and A - B, all the ordinary laws of addition and subtraction that hold in the algebra of real numbers hold also in the algebra of complex quantities. In particular, the zero point O has all the formal properties of the number zero, and is denoted by O.

[Note: If A and B are "real" points, A + B and A - B will also be real.

Repeated Addition. Multiples and Submultiples. The point $A + A + A + \dots + A$ to n terms is called the **nth multiple of A** and is denoted by nA. The points U, 2U, 3U, ... are denoted, for brevity, by 1, 2, 3, ... Conversely, if any point A, and any positive integer n are given, there is a definite point X such that nX = A; this point X is called the **nth submultiple of A**, and is denoted by

point X is called the **nth submultiple of A**, and is denoted by A/n. The points U/2, U/3, . . . are denoted, for brevity, by 1/2, 1/2, . . .

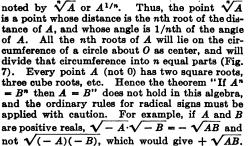

Multiplication and Division. The product, $A \times B$, or $A \cdot B$, or $A \cdot B$, or $A \cdot B$, of two points A and B is defined as the point whose angle is the sum of the angles of the given points, and whose distance is the product of the distances. (See Fig. 4.) Thus, if $A = (5, <120^{\circ})$ and $B = (2, <270^{\circ})$, then $AB = (10, <30^{\circ})$. Conversely, if any two points A and B are given, provided B is not zero, there is a definite point X such that

Fig. 4.

A = BX. This point X is called the quotient, A divided by B, and is denoted by A/B (where $B \neq 0$). Thus, the point A/B is a point whose angle is the angle of A minus the angle of B, and whose distance is the distance of A divided by the distance of B. The point U/B $(B \neq 0)$ is called the **reciprocal** of the point B, and is denoted by 1/B. (See Fig. 5.) With these definitions of AB and A/B the elementary laws of multiplication and division that hold in the algebra of real numbers hold also in the algebra of complex quantities. In particular, the point U has all the formal properties of the number unity, and is denoted by 1.

[Note: If A and B are real, AB and A/B will also be real.] Repeated Multiplication. Powers and Roots. point $A \times A \times A \times \dots \times A$ to n factors is called the nth power of A and is denoted by A^n (Fig. 6). Conversely,

if any point A (not 0) and any positive integer n are given, there will be n distinct points X such that $X^n = A$; each of these points is called an nth root of A, some one of them, usually the one with the smallest positive angle, being de-

[Note: If A is real and positive, $\sqrt[n]{A}$ will be real and positive; if A is real and negative, $\sqrt[n]{A}$ will be real if n. is odd and imaginary if n is even.

Properties of i. The point i is the point whose distance is 1 and whose angle is 90 deg. It follows from the definition above that **multiplying any point** \triangle by i has the effect of rotating the point through an angle of + 90° without changing its distance from O. In particular,

$$i^2 = -1$$
, $i^3 = -i$, $i^4 = 1$, $i^5 = i$, etc.; $i = \sqrt{-1}$, $-i = -\sqrt{-1}$; where "1" denotes not the number one, but the point U .

Similarly, multiplying any point A by -1 has the effect of rotating the point through 180 deg.

First Standard Form for a Complex Quantity (Fig. 8). Any point A can be expressed in the form x + iy, where x and y are real points. For example, the three cube roots of 1 are 1, $-\frac{1}{2} + \frac{1}{2}i\sqrt{3}$, and $-\frac{1}{2} - \frac{1}{2}i\sqrt{3}$.

Fig. 5.

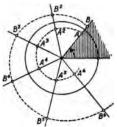

Fig. 6.

Fig. 7.

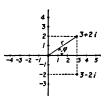

Fig. 8.

126 ALGEBRA

In general,
$$(x_1 + iy_1) + (x_2 + iy_2) = (x_1 + x_2) + i(y_1 + y_2);$$

 $(x_1 + iy_1)(x_2 + iy_2) = (x_1x_2 - y_1y_2) + i(x_2y_1 + x_1y_2);$

$$\frac{x_1 + iy_1}{x_2 + iy_2} = \frac{x_1x_2 + y_1y_2}{x_2^2 + y_2^2} + i \frac{x_2y_1 - x_1y_2}{x_2^2 + y_2^2}.$$

If two complex quantities are equal, their real parts must be equal, and the coefficients of their pure imaginary parts must also be equal. That is, if $x_1 + iy_1 = x_2 + iy_2$, then $x_1 = x_2$ and $y_1 = y_2$. Thus a single equation between complex quantities is equivalent to two equations between real quantities.

Conjugate Imaginaries. Two points A = x + iy and B = x - iy are called conjugate imaginaries. Two such points are symmetrically situated with regard to the axis of reals. The sum and product of two conjugate imaginaries will be real.

Second Standard Form for a Complex Quantity. Since $x = r \cos \varphi$ and $y = r \sin \varphi$, any point A = x + iy can be expressed $A = r (\cos \varphi + i \sin \varphi)$, where r is real and positive (namely, the distance of A), and φ is real (namely the angle of A). For example, the three cube roots of 1 are 1, $\cos 120^{\circ} + i \sin 120^{\circ}$, and $\cos 240^{\circ} + i \sin 240^{\circ}$. In general, $[r_1 (\cos \varphi_1 + i \sin \varphi_1)] [r_2 (\cos \varphi_2 + i \sin \varphi_2)] = r_1 r_2 [(\cos (\varphi_1 + \varphi_2) + i \sin (\varphi_1 + \varphi_2)]; [r(\cos \varphi + i \sin \varphi)]^n = r^n [\cos(n\varphi) + i \sin (n\varphi)]$ (De Moivre's Theorem).

The Exponential Function, e^A , or $\exp A$, of any point A = x + iy is defined as the point whose distance is e^x and whose angle (measured in radians) is y. That is, $e^{x+iy} = e^x(\cos y + i \sin y)$. Here e^x means the ordinary exponential function of the real quantity x, where $e^x = 2.718$.

From this definition, the usual formal laws of exponents can be deduced: $e^A e^B = e^{A+B}$, $(e^A)^n = e^{nA}$, $e^{-A} = 1/e^A$; $e^1 = e$, $e^0 = 1$.

The function e^A is a periodic function with a pure imaginary period $2\pi i$; that is, $e^A \pm k^2 \pi^i = e^A$, where k is any positive integer.

If A is made to move along a line parallel to the axis of reals [or axis of pure imaginaries], the corresponding point e^A will move along a straight line through O [or along a circle about O as center].

Properties of e^{i\varphi}. The point $e^{i\varphi}$ is a point whose distance is 1 and whose angle is φ . It follows from the definitions above that multiplying any point A by $e^{i\varphi}$ has the effect of rotating the point through an angle φ , without changing its distance from O. In particular, $e^{i\pi} = -1$, $e^{-i\pi} = -1$: $e^{i\pi/2} = i$; $e^{-i\pi/2} = -i$; $e^{2\pi i} = 1$.

Third Standard Form for a Complex Quantity. Any point A can be expressed in the form $A = re^{i\varphi}$, where r is the distance and φ the angle of the point. For example, the three cube roots of 1 are 1, $e^{\frac{i\pi r}{2}}$, $e^{\frac{i\pi r}{2}}$. In general,

$$(r_1e^{i\varphi_1})(r_2e^{i\varphi_2}) = (r_1r_2)e^{i(\varphi_1+\varphi_2)}; \quad (re^{i\varphi})^n = (r^n)e^{in\varphi}.$$
 If $x + iy = re^{i\varphi}$, then $r = \sqrt{x^2 + y^2}$, $\sin \varphi = \frac{y}{x}$, $\cos \varphi = \frac{x}{x}$, $\tan \varphi = \frac{y}{x}$.

If two complex quantities are equal, their distances will be equal, and their angles will differ at most by some multiple of 2π . Thus, if $r_1e^{i\varphi_1} = r_2e^{i\varphi_1}$ then $r_1 = r_2$ and $\varphi_1 = \varphi_2$ or $\varphi_2 \pm k2\pi$. Here again a single equation between complex quantities is equivalent to two equations between real quantities.

Definition of A^B. Let $A = re^{i\varphi}$; then $A^B = \exp[(\log_e r + i\varphi)B]$.

For example, $i^i = e^{-\pi/2}$ where $i = \sqrt{-1}$.

If a is a positive real, $a^{x+iy} = a^x [\cos(y \log_{\theta} a) + i \sin(y \log_{\theta} a)].$

Trigonometric and Hyperbolic Functions of a Complex Variable. If A is any point, then, by definition,

$$\sin A = \frac{e^{iA} - e^{-iA}}{2i}, \quad \cos A = \frac{e^{iA} + e^{-iA}}{2}, \quad \tan A = \frac{\sin A}{\cos A} \quad (\cos A \neq 0);$$

$$\sinh A = \frac{e^{A} - e^{-A}}{2}, \quad \cosh A = \frac{e^{A} + e^{-A}}{2}, \quad \tanh A = \frac{\sinh A}{\cosh A}.$$

Hence the formulæ that hold for these functions in the real case (p. 131; p. 135; p. 161) hold also for the complex case. Further:

$$\sin (x + iy) = \sin x \cosh y + i \cos x \sinh y,$$
 $\sin iy = i \sinh y;$
 $\cos (x + iy) = \cos x \cosh y - i \sin x \sinh y,$ $\cos iy = \cosh y;$
 $\sinh (x + iy) = \sinh x \cos y + i \cosh x \sin y,$ $\sinh iy = i \sin y;$
 $\cosh (x + iy) = \cosh x \cos y + i \sinh x \sin y,$ $\cosh iy = \cos y;$

where $\sin x$, $\sinh x$, etc., are the ordinary trigonometric and hyperbolic functions of the real variables x and y. The functions $\sin A$ and $\cos A$ are periodic with a real period 2π . The functions $\sinh A$ and $\cosh A$ are periodic with a pure imaginary period $2\pi i$.

Logarithmic and Other Inverse Functions of a Complex Variable. If any point A is given, there will be an infinite number of points X such that $e^X = A$; any one of these points may be called a logarithm of A, and be denoted by $\log A$. All the values of the logarithm of A may be obtained from any one value by adding multiples of $2\pi i$.

If $x + iy = re^{i\varphi}$, then $\log_e(x + iy) = \log_e r + i\varphi \pm k \cdot 2\pi i$.

If any point A is given, there will be an infinite number of points X such that $\sin X = A$; any one of these may be denoted by $\sin^{-1} A$. The functions $\cos^{-1} A$, $\sinh^{-1} A$, etc., are defined in a similar way.

The elementary laws of operation which hold for these functions in the algebra of reals hold also, in a general way, in the algebra of complex quantities; but caution must be used, on account of the ambiguity in the symbols $\log A$, $\sin^{-1}A$, etc., which denote many-valued functions.

Differentiation of Functions of a Complex Variable. If w = f(z), the derivative of w with respect to z is defined as

 $dw/dz = \lim \{ [f(z + \Delta z) - f(z)]/\Delta z \}$ when Δz approaches 0.

It can be shown that $\lim \{[\exp \Delta z - 1]/\Delta z\} = 1$; hence $d(e^z) = e^z dz$, $d(\sin z) = \cos z dz$, etc., so that the formulæ for differentiation here are the same as in the case of a real variable (p. 157).

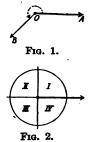

NOTE. For the algebra of vector analysis, which differs in important respects from the algebra of complex quantities, see p. 185.

TRIGONOMETRY

FORMAL TRIGONOMETRY

Angles, or Rotations. An angle is generated by the rotation of a ray, as Ox, about a fixed point O in the plane. Every angle has an **initial line** (OA) from which the rotation started (Fig. 1), and a **terminal line** (OB) where it stopped; and the counterclockwise direction of rotation is taken as

positive. Since the rotating ray may revolve as often as desired, angles of any magnitude, positive or negative, may be obtained. Two angles are congruent if they may be superposed so that their initial lines coincide and their terminal lines coincide. That is, two congruent angles are either equal or differ by some multiple of 360 deg. Two angles are complementary if their sum is 90 deg.; supplementary if their sum is 180 deg. (The acute angles of a right-angled triangle are complementary.) If the initial line is placed so that it runs horizontally to the right, as in Fig. 2, then the angle is said to be an angle in the 1st, 2nd, 3rd, or 4th quadrant according as the terminal line lies across the region marked I, II, III, or IV. The angles 0 deg., 90 deg., 180 deg., 270 deg. are called the quadrantal angles.

Units of Angular Measurement.

(1) SEXAGESIMAL MEASURE. (360 degrees = 1 revolution.) 1 degree = 1° = 160 of a right angle. The degree is usually divided into 60 equal parts called minutes ('), and each minute into 60 equal parts called seconds ("); while the second is subdivided decimally. But for many purposes it is more convenient to divide the degree itself into decimal parts, thus avoiding the use of minutes and seconds. (See tables, pp. 46-51.)

(2) CENTESIMAL MEASURE, used chiefly in France. (400 grades = 1 revolution.) 1 grade = 1/100 of a right angle. The grade is always divided decimally, the following terms being sometimes used: 1 "centesimal minute" = 1/100 of a grade; 1 "centesimal second" = 1/100 of a centesimal minute. In reading Continental books it is important to notice carefully which system is employed.

(3) Radian, or Circular, Measure. (π radians = 180 degrees.) 1 radian = the angle subtended by an arc whose length is equal to the length of the radius. The radian is constantly used in higher mathematics and in mechanics, and is always divided decimally. Table, pp. 44-45.

1 radian = $57^{\circ}.30 - = 57^{\circ}.2957795131 = 57^{\circ} 17' 44''.806247 = 180^{\circ}/\pi$.

 $1^{\circ} = 0.01745$. . . radian = 0.0174532925 radian.

 $1' = 0.00029\,08882\,\text{radian}$. $1'' = 0.00000\,48481\,\text{radian}$. (For 10-place conversion tables, see the Smithsonian Tables of Hyperbolic Functions, Washington, **D. C.**)

Definitions of the Trigonometric Functions. Let x be any angle whose initial line is OA and terminal line OP (see Fig. 3). Drop a perpendicular from P on OA or OA produced. In the right triangle OMP, the three sides

Fig. 3.

are MP = "side opposite" O (positive if running upward); OM = "side adjacent" to O (positive if running to the right); OP = "hypothenuse" or "radius" (may always be taken as positive); and the six ratios between these sides are the principal trigonometric functions of the angle x; thus:

```
sine of x = \sin x = \text{opp/hyp} = MP/OP;

cosine of x = \cos x = \text{adj/hyp} = OM/OP;

tangent of \dot{x} = \tan x = \text{opp/adj} = MP/OM;

cotangent of x = \cot x = \text{adj/opp} = OM/MP;

secant of x = \sec x = \text{hyp/adj} = OP/OM;

cosecant of x = \cos x = \text{hyp/opp} = OP/MP.
```

The last three are best remembered as the reciprocals of the first three: $\cot x = 1/\tan x$; sec $x = 1/\cos x$; csc $x = 1/\sin x$.

Other functions in use are the versed sine, the coversed sine, and the exterior secant:

vers $x = 1 - \cos x$; covers $x = 1 - \sin x$; exsec $x = \sec x - 1$. For graphs, see p. 174; series, p. 161.

Signs of the Trigonometric Functions

If x is in quadrant	I	II	III	IV
sin x and csc x are	l +	+ -	- - +	+

vers x and covers x are always positive.

Variations in the Functions as x Varies from 0 deg. to 360 deg. are shown in the accompanying table. The variations in the sine and cosine are

Fig. 4.

best remembered by noting the changes in the lines MP and OM (Fig. 4) in the "unit circle" (that is, a circle with radius = OP = 1), as P moves around the circumference.

	00000	000 4 - 1000	1000 0000	270° to 360°	Values at		
æ	0° to 90°	90° to 180°	180° to 270°		30°	45°	60°
sin x	+0 to +1 + ∞ to +1	+1 to +0 +1 to +∞	-0 to -1 -∞ to -1	-1 to -0 -1 to -∞	1,2		}½√3 ¾√8
cos X sec x	+1 to +0 +1 to +∞	-0 to -1 -∞ to -1	-1 to -0 -1 to -∞	+0 to +1 + ∞ to +1	1/2√3 3/2√3	$\sqrt[32]{\frac{\sqrt{2}}{\sqrt{2}}}$	
tan x	+0 to + ∞ + ∞ to +0	- \infty to -0 -0 to - \infty	+0 to + ∞ + ∞ to +0	- ∞ to -0. -0 to - ∞	14√3 √3	1	√ <u>3</u> ⅓√8
vers x	+0 to +1 +1 to +0	+1 to +2 +0 to +1	+2 to +1 +1 to +2	+1 to +0 +2 to +1			

$$\sqrt{2}$$
 = 1.4142; $\frac{1}{2}\sqrt{2}$ = 0.7071; $\sqrt{3}$ = 1.7321; $\frac{1}{2}\sqrt{3}$ = 0.8660; $\frac{1}{2}\sqrt{3}$ = 0.5774; $\frac{3}{2}\sqrt{3}$ = 1.1547

Trigonometrical Tables. The tables on pp. 46-56 give the values of the principal trigonometric functions and of their logarithms, correct to four places of decimals, the angle advancing either by tenths of a degree (p. 46) or by 10 min. (p. 52). These tables will be found adequate for most

computations in which an accuracy of 1 part in 1000 is sufficient. If much computing is to be done, it is advisable to use a separate volume of tables, containing more facilities for interpolation, and printed in larger type, such as the four-place tables of E. V. Huntington (Harvard Coöperative Society, Cambridge, Mass.), with convenient marginal tabs; the five-place tables published by Macmillan or many others; the six-place tables of Bremiker; the standard seven-place tables of Schrön, Vega, or Bruhns (angles advancing by 10 sec.); or the great eight-place of Bauschinger and Peters (angles advancing at intervals of 1 sec. from 0 deg. to 90 deg.). The larger tables give only the logarithms of the functions, not the natural values.

To Find Any Function of a Given Angle. (Reduction to the first quadrant.) It is often required to find the functions of any angle x from a table that includes only angles between 0 deg. and 90 deg. If x is not already between 0 deg. and 360 deg., first "reduce to the first revolution" by simply adding or subtracting the proper multiple of 360 deg.; [for any function of (x) = the same function of $(x \pm n \times 360^{\circ})$]. Next reduce to the first quadrant as follows:

If x is between Subtract		90° and 180°	180° and 270°	270° and 360° 270° from x	
		90° from x	180° from <i>x</i>		
Then	sin x	= $+\sec (x-90^{\circ})$ = $-\sin (x-90^{\circ})$ = $-\csc (x-90^{\circ})$	$ \begin{array}{l} -\sin (x-180^{\circ}) \\ -\cos (x-180^{\circ}) \\ -\cos (x-180^{\circ}) \\ -\cos (x-180^{\circ}) \\ -\sec (x-180^{\circ}) \\ +\tan (x-180^{\circ}) \\ -\cot (x-180^{\circ}) \end{array} $	$ \begin{array}{l}\cos (x-270^{\circ}) \\\sec (x-270^{\circ}) \\ -+\sin (x-270^{\circ}) \\ -+\cos (x-270^{\circ}) \\\cot (x-270^{\circ}) \\\tan (x-270^{\circ}) \end{array} $	
	vers x	$= 1 + \sin (x - 90^{\circ})$ = 1 - \cos (x - 90^{\circ})	$=1+\cos (x-180^{\circ})$ = $1+\sin (x-180^{\circ})$	$=1-\sin (x-270\%)$ =1+\cos (x-270\cdot)	

The "reduced angle" $(x - 90^{\circ}, \text{ or } x - 180^{\circ}, \text{ or } x - 270^{\circ})$ will in each case be an angle between 0° and 90°, whose functions can then be found in the table.

[Note. The formulæ for sine and cosine are best remembered by aid of the unit circle.]

To Find the Angle When One of Its Functions is Given. In general, there will be two angles between 0 deg. and 360 deg. corresponding to any given function. The following tabulated rules show how to find these angles.

Given	First find from the tables an acute angle ze such that	Then the required angles x and x: will be
$\sin x = +a$	$\sin x_0 = a$	xe and 180°-xe
$\cos x = +a$	$\cos x_0 = a$	x_0 and $[360^\circ - x_0]$
$\tan x = +a$	$\tan x_0 = a$	x_0 and $\begin{bmatrix} 180^\circ + x_0 \end{bmatrix}$ x_0 and $\begin{bmatrix} 180^\circ + x_0 \end{bmatrix}$
$\cot x = +a$	$\cot x_0 = a$	x_0 and $[180^\circ + x_0]$
$\sin x = -a$	$\sin x_0 = a$	[180°+x ₀]and [360°-x ₀] 180°-x ₀ and [180°+x ₀]
$\cos x = -a$	$\cos x_0 = a$	$180^{\circ} - x_0$ and $(180^{\circ} + x_0)$
$\tan x = -a$	$\tan x_0 = a$	180° — za and [360° — za]
$\cot x = -a$	$\cot x_0 = a$	180°-ze and [360°-ze]

The angles enclosed in brackets lie outside the range from 0 deg. to 180 deg., and hence cannot occur as angles in a triangle.

For solution of trigonometric equations, see p. 118.

Relations Between the Functions of a Single Angle. (See Fig. 5.)

$$\sin^{2} x + \cos^{2} x = 1; \tan x = \frac{\sin x}{\cos x}; \cot x = \frac{1}{\tan x} = \frac{\cos x}{\sin x};$$

$$1 + \tan^{2} x = \sec^{2} x = \frac{1}{\cos^{2} x}; 1 + \cot^{2} x = \csc^{2} x = \frac{1}{\sin^{2} x};$$

$$\sin x = \sqrt{1 - \cos^{2} x} = \frac{\tan x}{\sqrt{1 + \tan^{2} x}} = \frac{1}{\sqrt{1 + \cot^{2} x}};$$

$$\cos x = \sqrt{1 - \sin^{2} x} = \frac{1}{\sqrt{1 + \tan^{2} x}} = \frac{\cot x}{\sqrt{1 + \cot^{2} x}};$$
Functions of Negative Angles. $\sin (-x) = -\sin x;$

$$\cos x = \sqrt{1 - \sin^{2} x} = \frac{1}{\sqrt{1 + \cot^{2} x}};$$

 $\cos(-x) = \cos x$; $\tan(-x) = -\tan x$.

Functions of the Sum and Difference of Two Angles.

F1g. 5.

```
\sin (x + y) = \sin x \cos y + \cos x \sin y;
\cos(x+y) = \cos x \cos y - \sin x \sin y;
\tan(x+y) = [\tan x + \tan y]/[1 - \tan x \tan y];
\cot (x+y) = [\cot x \cot y - 1]/[\cot x + \cot y];
\sin (x - y) = \sin x \cos y - \cos x \sin y;
\cos(x-y)=\cos x\cos y+\sin x\sin y;
\tan(x-y) = [\tan x - \tan y]/[1 + \tan x \tan y];
\cot (x - y) = [\cot x \cot y + 1]/[\cot y - \cot x];
\sin x + \sin y = 2 \sin \frac{1}{2}(x + y) \cos \frac{1}{2}(x - y);
\sin x - \sin y = 2 \cos \frac{1}{2}(x + y) \sin \frac{1}{2}(x - y);
\cos x + \cos y = 2 \cos \frac{1}{2}(x + y) \cos \frac{1}{2}(x - y);
\cos x - \cos y = -2 \sin \frac{1}{2}(x+y) \sin \frac{1}{2}(x-y);
\tan x + \tan y = \frac{\sin (x + y)}{\cos x \cos y}; \cot x + \cot y = \frac{\sin (x + y)}{\sin x \sin y};
\tan x - \tan y = \frac{\sin (x - y)}{\cos x \cos y}; \cot x - \cot y = \frac{\sin (y - x)}{\sin x \sin y};
\sin^2 x - \sin^2 y = \cos^2 y - \cos^2 x = \sin (x + y) \sin (x - y);
\cos^2 x - \sin^2 y = \cos^2 y - \sin^2 x = \cos (x + y) \cos (x - y);
\sin (45^{\circ} + x) = \cos (45^{\circ} - x); \tan (45^{\circ} + x) = \cot (45^{\circ} - x);
\sin (45^{\circ} - x) = \cos (45^{\circ} + x): \tan (45^{\circ} - x) = \cot (45^{\circ} + x).
```

In the following transformations, a and b are supposed to be positive, $c = \sqrt{a^2 + b^2}$, A = the positive acute angle for which tan A = a/b, and B = the positive acute angle for which tan B = b/a: $a\cos x + b\sin x = c\sin(A + x) = c\cos(B - x);$ $a\cos x - b\sin x = c\sin (A - x) = c\cos (B + x).$

Functions of Multiple Angles and Half Angles.

$$\sin (nx) = n \sin x \cos^{n-1} x - (n)_3 \sin^2 x \cos^{n-3} x + (n)_5 \sin^5 x \cos^{n-5} x - \dots + (n)_5 \sin^{n-5} x - \dots + (n)_5 \sin^{n-5} x - \dots + (n)_5 \sin^{n-5} x -$$

Here the + or - sign is to be used according to the sign of the left-hand side of the equation.

Relations Between Three Angles Whose Sum is 180°. $\sin A + \sin B + \sin C = 4 \cos \frac{1}{2}A \cos \frac{1}{2}B \cos \frac{1}{2}C$; $\cos A + \cos B + \cos C = 4 \sin \frac{1}{2}A \sin \frac{1}{2}B \sin \frac{1}{2}C + 1$; $\sin A + \sin B - \sin C = 4 \cos \frac{1}{2}A \cos \frac{1}{2}B \sin \frac{1}{2}C - 1$; $\sin^2 A + \sin^2 B + \sin^2 C = 2 \cos A \cos B \cos C + 2$; $\sin^2 A + \sin^2 B - \sin^2 C = 2 \sin A \sin B \cos C$; $\tan A + \tan B + \tan C = \tan A \tan B \tan C$; $\cot \frac{1}{2}A + \cot \frac{1}{2}B + \cot \frac{1}{2}C = \cot \frac{1}{2}A \cot \frac{1}{2}B \cot \frac{1}{2}C$; $\cot A \cot B + \cot A \cot C + \cot B \cot C = 1$; $\sin 2A + \sin 2B + \sin 2C = 4 \cos A \cos B \sin C$; $\sin 2A + \sin 2B - \sin 2C = 4 \cos A \cos B \sin C$.

Inverse Trigonometric Functions. The notation $\sin^{-1}x$ (read: antisine of x, or inverse sine of x; sometimes written are $\sin x$) means the principal angle whose sine is x. Similarly for $\cos^{-1}x$, $\tan^{-1}x$, etc. (The principal angle means an angle between -90° and $+90^{\circ}$ in case of \sin^{-1} and \tan^{-1} , and between 0° and 180° in the case of \cos^{-1} .) For graphs, see p. 174.

SOLUTION OF PLANE TRIANGLES

The "parts" of a plane triangle are its three sides, a, b, c, and its three angles A, B, C (A being opposite a, B opposite b, C opposite c, and $A+B+C=180^{\circ}$). A triangle is, in general, determined by any three parts (not all angles). To "solve" a triangle means to find the unknown parts from the known. The fundamental formulæ are:

Law of sines:
$$\frac{a}{b} = \frac{\sin A}{\sin B}$$
. Law of cosines: $c^2 = a^2 + b^2 - 2ab \cos C$.

Right Triangles. Use the definitions of the trigonometric functions, selecting for each unknown part a relation which connects that unknown with known quantities: then solve the resulting equations. Thus, in Fig. 6, if $C=90^{\circ}$, then $A + B = 90^{\circ}$, $c^{\circ} = a^{\circ} + b^{\circ}$.

If A is very small use tax had = \ \((e - \) \(e - \).

Oblique Triangles. There are four cases. It is highly desirable in all these cases to draw a sketch of the triangle approximately to scale before commencing the computation so that any large numerical error may be readily detected.

Case 1. Great Two Ayes as (provided their sum is < 180 dec.), and the

Side (say a, Fig. 7). The third angle is known, since $A + B + C = 180^{\circ}$.

 $\frac{a \sin B}{\sin A}, c = \frac{a \sin C}{\sin A}.$ To find the remaining sides, use b =

Or, drop a perpendicular from either B or C on the opposite side, and solve by right triangles.

Check: $c \cos B + b \cos C = a$.

Case 2. Given Two Sides (say a and b), and the Included Angla (C); and suppose a > b. Fig. 8.

First Method: Find c from $c^2 = a^2 + b^2 - 2ab \cos C$ [or $c^2 = (a - b)^2 + b^2 + b^2 + b^2 = ab \cos C$ 2ab vers C]; then find the smaller angle, B, from $\sin B = (b/c) \sin C$; and finally, find A from $A = 180^{\circ} - (B + C)$. Check: $a \cos B + b \cos A = c$. Second Method: Find $\frac{1}{2}(A - B)$ from the law of tangents:

$$\tan \frac{1}{2}(A - B) = [(a - b)/(a + b)] \cot \frac{1}{2}C$$

and $\frac{1}{2}(A + B)$ from $\frac{1}{2}(A + B) = 90^{\circ} - C/2$; hence A = $\frac{1}{2}(A+B) + \frac{1}{2}(A-B)$ and $B = \frac{1}{2}(A+B) - \frac{1}{2}(A-B)$. Then find c from $c = a \sin C/\sin A$ or $c = b \sin C/\sin B$. Check: $a \cos B + b \cos A = c$.

Third Method: Drop a perpendicular from A to the opposite side, and solve by right triangles.

Case 3. GIVEN THE THREE SIDES (provided the largest is less than the sum of the other two), Fig. 9.

First Method: Find the largest angle A (which may be acute or obtuse) from $\cos A = (b^2 + c^2 - a^2)/2bc$ {or vers $A = [a^2 - (b - c)^2]/2bc$ } and then find B and C (which will always be acute) from $\sin B = b \sin A/a$ and $\sin C = c \sin A/a$. Check: $A + B + C = 180^{\circ}$.

Second Method: Find A, B, and C from $\tan \frac{1}{2}A = r/(s-a)$,

 $\tan \frac{1}{2}B = r/(s-b)$, $\tan \frac{1}{2}C = r/(s-c)$, where $s = \frac{1}{2}(a+b+c)$, and $r = \sqrt{(s-a)(s-b)(s-c)/s}$. Check: $A+B+C=180^{\circ}$. Third Method: If only one angle, say A, is required, use

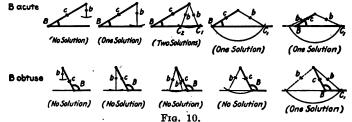

$$\sin \frac{1}{2}A = \frac{\sqrt{(s-b)(s-c)/bc}}{\cos \frac{1}{2}A} = \frac{\sqrt{s(s-a)/bc}}{\sqrt{s(s-a)/bc}},$$

according as $\frac{1}{2}A$ is nearer 0° or nearer 90° .

Case 4. Given Two Sides (say b and c) and the Angle OPPOSITE ONE OF THEM (B). This is the "ambiguous

case" in which there may be two solutions, or one, or none (see Fig. 10).

First, try to find C from $\sin C = c \sin B/b$. If $\sin C > 1$, there is no solution. If sin C = 1, $C = 90^{\circ}$ and the triangle is a right triangle. If sin C < 1, this determines two angles C, namely, an acute angle C_1 , and an obtuse angle $C_2 = 180^{\circ} - C_1$. Then C_1 will yield a solution when and only when

 $C_1 + B < 180^{\circ}$ (see Case 1); and similarly C_2 will yield a solution when and only when $C_2 + B < 180^{\circ}$ (see Case 1).

Other Properties of Triangles. (See also p. 99 and p. 105.)

Area =
$$\frac{1}{2}ab \sin C = \sqrt{s(s-a)(s-b)(s-c)} = rs$$
, where $s = \frac{1}{2}(a+b+c)$,

and $r = \text{radius of inscribed circle} = \sqrt{(s - a)(s - b)(s - c)/s}$.

Radius of circumscribed circle = R, where

$$2R = a/\sin A = b/\sin B = c/\sin C$$
; $r = 4R \sin \frac{A}{2} \sin \frac{B}{2} \sin \frac{C}{2} = \frac{abc}{4Rs}$.

The length of the bisector of the angle C is

$$z = \frac{2\sqrt{abs(s-c)}}{a+b} = \frac{\sqrt{ab[(a+b)^2-c^2]}}{a+b}.$$

The median from C to the middle point of c is $m = \frac{1}{2}\sqrt{2(a^2 + b^2) - c^2}$.

SOLUTION OF SPHERICAL TRIANGLES

For the occasional solution of a spherical triangle the following formulæ will be sufficient. For a detailed discussion, see any text-book on spherical trigonometry.

Let a, b, c be the sides of the spherical triangle, that is, portions of arcs of great circles of the sphere; and let A, B, C be the angles of the triangle, that is, the angles made by tangents drawn to the sides at their points of intersection on the sphere. The sum of the angles will always be greater than two right angles, and may be nearly six right angles. The angle $E = A + B + C - 180^{\circ}$ is called the **spherical excess** of the triangle. (See also p. 100.)

$$\frac{\sin a}{\sin A} = \frac{\sin b}{\sin B}; \qquad \frac{\sin b}{\sin B} = \frac{\sin c}{\sin C}; \qquad \frac{\sin c}{\sin C} = \frac{\sin a}{\sin A}.$$

 $\cos a = \cos b \cos c + \sin b \sin c \cos A$,

with similar formulæ for cos b and cos c.

$$\cos A = -\cos B \cos C + \sin B \sin C \cos a$$

with similar formulæ for $\cos B$ and $\cos C$.

In the special case of a right spherical triangle, in which $C = 90^{\circ}$,

$$\cos c = \cos a \cos b = \cot A \cot B$$
; $\cos a = \frac{\cos A}{\sin B}$; $\cos b = \frac{\cos B}{\sin A}$;

$$\sin A = \frac{\sin a}{\sin c}$$
; $\cos A = \frac{\tan b}{\tan c}$; $\tan A = \frac{\tan a}{\sin b}$.

$$\frac{\text{The area of a spherical triangle}}{\text{area of a great circle}} = \frac{\text{spherical excess}}{180^{\circ}}.$$

HYPERBOLIC FUNCTIONS

The hyperbolic sine, hyperbolic cosine, etc., of any number x, are functions of x which are closely related to the exponential e^x , and which have formal properties very similar to those of the trigonometric functions, sine, cosine, etc. Their definitions and fundamental properties are as follows (see also p. 127; graphs, p. 175; table, p. 60; series, p. 161):

```
\sinh x = \frac{1}{2}(e^x - e^{-x}); \cosh x = \frac{1}{2}(e^x + e^{-x}); \tanh x = \sinh x/\cosh x; \operatorname{csch} x = 1/\sinh x; \operatorname{sech} x = 1/\cosh x; \coth x = 1/\tanh x; \operatorname{cosh}^2 x - \sinh^2 x = 1; 1 - \tanh^2 x = \operatorname{sech}^2 x; 1 - \coth^2 x = -\operatorname{csch}^2 x; \sinh (-x) = -\sinh x; \cosh (-x) = \cosh x; \tanh (-x) = -\tanh x; \sinh (x \pm y) = \sinh x \cosh y \pm \cosh x \sinh y; \cosh (x \pm y) = \cosh x \cosh y \pm \sinh x \sinh y; \tanh (x \pm y) = (\tanh x \pm \tanh y)/(1 \pm \tanh x \tanh y); \sinh 2x = 2 \sinh x \cosh x; \cosh 2x = \cosh^2 x + \sinh^2 x; \tanh 2x = (2 \tanh x)/(1 + \tanh^2 x); \sinh \frac{1}{2}x = \sqrt{\frac{1}{2}(\cosh x - 1)}; \cosh \frac{1}{2}x = \sqrt{\frac{1}{2}(\cosh x + 1)}; \tanh \frac{1}{2}x = (\cosh x - 1)/(\sinh x) = (\sinh x)/(\cosh x + 1).
```

The inverse hyperbolic sine of y, denoted by $\sinh^{-1}y$, is the number whose hyperbolic sine is y; that is, the notation $x = \sinh^{-1}y$ means $\sinh x = y$. Similarly for $\cosh^{-1}y$, $\tanh^{-1}y$, etc. These functions are closely related to the logarithmic function, and are especially valuable in the integral calculus. For graphs, see p. 175.

$$\begin{array}{ll} \sinh^{-1}(y/a) &= \log_{e}(y + \sqrt{y^{2} + a^{2}}) - \log_{e} a; \\ \cosh^{-1}(y/a) &= \log_{e}(y + \sqrt{y^{2} - a^{2}}) - \log_{e} a; \\ \tanh^{-1}\frac{y}{a} &= \frac{1}{2}\log_{e}\frac{a + y}{a - y}; \quad \coth^{-1}\frac{y}{a} &= \frac{1}{2}\log_{e}\frac{y + a}{y - a}. \end{array}$$

The **anti-gudermannian** of an angle u, denoted by $gd^{-1}u$, is a number defined by $gd^{-1}u = \log_e \tan (\frac{1}{4}\pi + \frac{1}{2}u) = \int \sec u \ du$. When u is small, $gd^{-1}u = u + \frac{1}{2}u^3 + \frac{1}{2}u^5 + \frac{6}{2}\omega_{040}u^7 + \dots$.

ANALYTICAL GEOMETRY

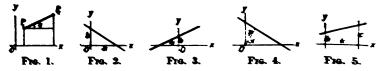

THE POINT AND THE STRAIGHT LINE

Rectangular Co-ordinates (Fig. 1). Let $P_1 = (x_1, y_1)$, $P_2 = (x_2, y_2)$. Then, distance $P_1P_2 = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$; slope of $P_1P_2 = m = \tan u = (y_1 - y_1)/(x_1 - x_1)$; co-ordinates of mid-point are $x = \frac{y_1}{x_1}(x_1 + x_2)$, $y = \frac{y_1}{y_1}(y_1 + y_2)$; co-ordinates of point (1/n)th of the way from P_1 to P_2 are $x = x_1 + (1/n)(x_2 - x_1)$, $y = y_1 + (1/n)(y_2 - y_1)$.

Let m_1 , m_2 be the slopes of two lines; then, if the lines are parallel, $m_1 = m_2$; if the lines are perpendicular to each other, $m_1 = -1/m_2$.

Equations of a Straight Line.

- 1. Intercept Form (Fig. 2): $\frac{x}{a} + \frac{y}{b} = 1$. (a, b = intercepts of the line on the axes.)
- 2. Slope Form (Fig. 3): y = mx + b. ($m = \tan u = \text{slope}$; b = intercept on the y-axis; see also Fig. 2, p. 174.)
- 3. Normal Form (Fig. 4): $x \cos v + y \sin v = p$. (p = perpendicular from origin to line; v = angle p makes with the x-axis.)
- 4. Parallel-intercept Form (Fig. 5): $\frac{y-b}{c-b} = \frac{x}{k}$. (b, c = intercepts on two parallels at distance k apart.)

- 5. General Form: Ax + By + C = 0. [Here a = -CA, b = -CB, m = -AB, $\cos x = AB$, $\sin x = BB$, p = -CB, where $B = \pm \sqrt{A^2 + B^2}$ (sign to be so obosen that p is positive).]
 - 6. Line Through (x_i, y_i) with Slope $m: y y_i = m(x x_i)$.
 - 7. Line Through (x_1, y_1) and (x_2, y_2) : $y y_1 = \frac{y_2 y_1}{x_2 x_2}(x x_2)$.
 - 8. Line Parallel to x-axis: x = a; to y-axis: y = b. Angles and Distances.

If w = angle between two lines whose slopes are mi. ms. then

$$\tan u = \frac{m_0 - m_1}{1 + m_0 m_1}$$
 If parallel, $m_1 = m_2$.

If perpendicular, $m_1 = -1$.

If u = angle between the lines Ax + By + C = 0 and A'x + B'y + C' = 0.

$$AA' + BB' \qquad \text{If parallel, } AA' = BB'.$$

$$\frac{\pm \sqrt{(A^2 + B^2) \cdot (A^2 + B^2)}}{4 + \sqrt{(A^2 + B^2)}} \qquad \text{If perpendicular, } AA' + BB' = 0.$$

The equations of the bisectors of the angles between the two lines just mentioned are

$$\frac{Ax + By + C}{\sqrt{A^2 + B^2}} = \frac{A^2x + B^2y + C^2}{\sqrt{A^2 + B^2}} = 0.$$

The equation of a line through (x_1, y_1) and meeting a given line y = mx + bat an angle u, is

$$y - y_1 = \frac{m + \tan u}{1 - m \tan u} (x - x_1).$$

The distance from (x_0, y_0) to the line Ax + By + C = 0 is

$$D = \left| \frac{Ax_0 + By_0 + C}{\sqrt{A^2 + B^2}} \right|$$

where the vertical bars mean "the absolute value of."

The distance from (x_0, y_0) to a line which passes through (x_1, y_1) and makes an angle u with the x-axis, is

$$D = (x_0 - x_1) \sin u - (y_0 - y_1) \cos u.$$

Polar Co-ordinates (Fig. 6). Let (x, y) be the rectangular and (r, θ) the polar co-ordinates of a given point P. Then $x = r \cos \theta$; $y = r \sin \theta$; $x^2 + y^2 = r^2$.

Transformation of Co-ordinates. If origin is moved to point (x_0, y_0) , the new axes being parallel to the old, $x = x_0 + x', y = y_0 + y'.$

If axes are turned through the angle u, without change of origin,

$$x = x' \cos u - y' \sin u$$
, $y = x' \sin u + y' \cos u$.

THE CIRCLE

(See also pp. 99, 103-105, 106)

Equation of Circle with center (a,b) and radiu r:

$$(x-a)^2 + (y-b)^2 = r^2$$
.

If center is at the origin, the equation becomes $x^2 + y^2 = r^2$. If circle goes through the origin and center is on the x-axis at point (r, 0), equation becomes $x^2 + y^2 = 2rx$. The general equation of a circle is

$$x^2 + y^2 + Dx + Ey + F = 0$$
; it has center at $(-D/2, -E/2)$, and radius $= \sqrt{(D/2)^2 + (E/2)^2 - F}$ (which may be real, null, or imaginary).

The equation of the radical axis of two circles, $x^2 + y^2 + Dx + Ey +$ F = 0 and $x^2 + y^2 + D'x + E'y + F' = 0$, is (D - D')x + (E - E')y +(F - F') = 0. The tangents drawn to two circles from any point of their radical axis are of equal length. If the circles intersect, the radical axis passes through their points of intersection (see p. 100).

The equation of the tangent to $x^2 + y^2 = r^2$ at (x_1, y_1) is $x_1x + y_1y = r^2$. The tangent to $x^2 + y^2 + Dx + Ey + F = 0$ at (x_1, y_1) is $x_1x + y_1y + \frac{1}{2}D(x + x_1) + \frac{1}{2}E(y + y_1) + F = 0$. The line y = mx + bwill be tangent to the circle $x^2 + y^2 = r^2$ if $b = 1/1 + m^2$.

Equations of Circle in Parametric Form. It is sometimes convenient to express the co-ordinates x and y of the moving point P(Fig. 7) in terms of an auxiliary variable, called a parameter. Thus, if the parameter be taken as the angle u which the radius OP makes with the x-axis, then the equations of the

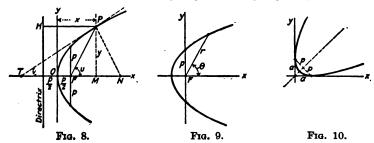

circle in parametric form will be $x = a \cos u$; $y = a \sin u$. For every value of the parameter u, there corresponds a point (x, y) on the circle. The ordinary equation $x^2 + y^2 = a^2$ can be obtained from the parametric equations by eliminating u.

Fig. 7.

THE PARABOLA

The parabola (see also p. 107) is the locus of a point which moves that its distance from a fixed line (called the directrix) is always equal to its distance from a fixed point F (called the focus). See Fig. 8. The point half-way from iocus to directrix is the vertex, O, The line through the focus, perpendicular to the directrix, is the principal axis. The breadth of the curve at the focus is called the latus rectum, or parameter, = 2p, where p is the distance from focus to directrix. (Compare also Fig. 3, p. 174.)

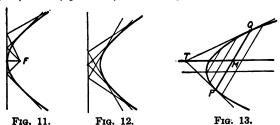

Any section of a right circular cone made by a plane parallel to a tangent plane of the cone will be a parabola.

Equation of Parabola, origin at vertex (Fig. 8): $y^2 = 2px$.

Polar Equation of Parabola, referred to F as origin and Fx as axis (Fig. 9): $r = p/(1 - \cos \theta)$.

Equation Referred to the Tangents at the ends of the latus rectum as axes (Fig. 10): $x^{\frac{1}{2}} + y^{\frac{1}{2}} = a^{\frac{1}{2}}$, where $a = p\sqrt{2}$.

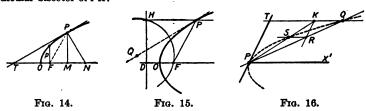

Equation of Tangent to $y^2 = 2px$ at (x_1,y_1) : $y_1y = p(x + x_1)$. The line y = mx + b will be tangent to $y^2 = 2px$ if b = p/(2m).

The tangent PT at any point P bisects the angle between PF and PH (Fig. 8). A ray of light from F, reflected at P, will move off parallel to the principal axis. The subtangent, TM, is bisected at O. The subnormal, MN, is constant, and equal to p. The locus of the foot of the perpendicular from the focus on a moving tangent is the tangent at the vertex (Fig. 11). The locus of the point of intersection of perpendicular tangents is the directrix (Fig. 12). The locus of the mid-points of a set of parallel chords whose alope is m is a straight line parallel to the principal axis at a distance p/m.

and is called a **diameter** (Fig. 13). If M is the mid-point of a chord PQ, and if T is the point of intersection of the tangents at P and Q, then TM is parallel to the principal axis, and is bisected by the curve (Fig. 13).

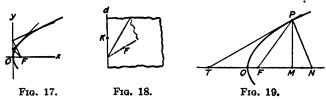

To Construct a Tangent to a Given Parabola. (1) At a given point of contact, P (Fig. 14): Find T so that OT = OM, or FT = FP. Then TP is the tangent at P. Or, make MN = p = 2(OF); then PN is the normal at P.

(2) From a given external point, Q (Fig. 15): With Q as center and radius QF draw circle cutting the directrix in H; draw HP parallel to principal axis; then P is required point of contact. As check, note that QP is the perpendicular bisector of FH.

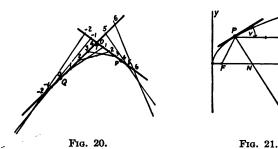

To Construct a Parabola. 1. Given Any Two Points, P and Q the Tangent PT at One of Them, and the Direction of the Principal Alis OX. In Fig. 16, let K be a variable point on a line through Q parallel to OX. Draw KR parallel to PT (meeting PQ in R), and draw RS parallel to OX (meeting PK in S); then S is a point of the curve. Note. A line through P parallel to the principal axis bisects all chords parallel to the tangent PT.

2. GIVEN THE VERTEX O AND FOCUS F. (a) In Fig. 17 draw O_F perpendicular to O_F , and slide the vertex of a right angle along O_F so that one side always passes through F; then the other side will always be a tangent to the parabola.

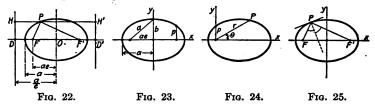

- (b) Take a piece of paper (Fig. 18) with a straight edge, d, and mark a point F near the edge. Let K be a variable point of the edge, and fold the paper so that K coincides with F. The crease will be a tangent to the parabola which has focus F and directrix d.
- (c) In Fig. 19, let M be a variable point of the principal axis, and lay off MN = 2(OF) = p. With F as center and radius FN draw a circle, cutting the perpendicular at M in P. Then P is a point of the curve, and PT and PN are the tangent and normal at P.
- 3. GIVEN TWO TANGENTS AND THEIR POINTS OF CONTACT, P AND Q (Fig. 20). Divide TP and QT into any number of equal parts (here 4). Then the lines 11, 22, 33, . . . will be tangents to the parabola. This method is especially advantageous in drawing rather flat arcs.

The Radius of Curvature of $y^2 = 2px$ at a point P = (x,y) is $R = (p + 2x)^{3/2}/\sqrt{p}$, or $R = p/\sin^3 v$, where v = the angle which the tangent at P makes with PF (Fig. 21). At the vertex, R = p. To construct the radius of curvature at any point P, lay off PR = 2(PF) parallel to the principal axis, and draw RC perpendicular to the axis, meeting the normal, PN, in C. Then C is the center of curvature for the point P, and a circle about C with radius CP will coincide closely with the parabola in the neighborhood of P.

THE ELLIPSE

The ellipse (see also p. 107) has two foci, F and F' (Fig. 22), and two directrices, DH and D'H'. If P is any point of the curve, PF + PF' is constant, $-2e_T$ and PF/PH (or PF'/PH') is also constant, $-e_t$, where e is the eccentricity (e < 1). Either of these properties may be taken as the definition of the curve. The relations between e and the semi-axes a and b are as shown in Fig. 23. Thus, $b^2 = a^2(1 - e^2)$, $ae = \sqrt{a^2 - b^2}$, $e^2 = 1 - (b/a)^2$. The semi-latus rectum $= p = a(1 - e^2) = b^2/a$. Note that b is always less than a, except in the special case of the circle, in which b = a and e = 0.

Any section of a right circular cone made by a plane which cuts all the elements of one nappe of the cone will be an ellipse; if the plane is perpendicular to the axis of the cone, the ellipse becomes a circle.

Equation of Ellipse, center as origin:

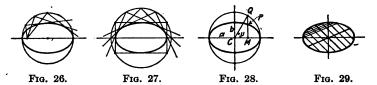

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$
, or $y = \pm \frac{b}{a} \sqrt{a^2 - x^2}$.

If P = (x, y) is any point of the curve, PF = a + ex, PF' = a - ex.

Equations of the Ellipse in Parametric Form: $x = a \cos u$, $y = b \sin u$, where u is the eccentric angle of the point P = (x,y). See Fig. 28.

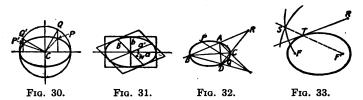

Polar Equation, focus as origin, axes as in Fig. 24: $r = p/(1 - \epsilon \cos \theta)$. **Equation of the Tangent** at (x_1, y_1) : $b^2x_1x + a^2y_1y = a^2b^2$.

The line y = mx + k will be a tangent if $k = \pm \sqrt{a^2m^2 + b^2}$. The normal at any point P bisects the angle between PF and PF' (Fig. 25). The locus of the foot of the perpendicular from the focus on a moving tangent is the circle on the major axis as diameter (Fig. 26). The locus of the point of intersection of perpendicular tangents is a circle with radius $\sqrt{a^2 + b^2}$ (Fig. 27).

Ellipse as a Flattened Circle. Eccentric Angle. If the ordinates in a circle are diminished in a constant ratio, the resulting points will lie on an ellipse (Fig. 28). If Q traces the circle with uniform velocity, the corresponding point P will trace the ellipse, with varying velocity. The angle u in the figure is called the eccentric angle of the point P.

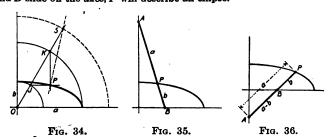

Conjugate Diameters are lines through the center, each of which bisects all the chords parallel to the other (Fig. 29). If m_1 and m_2 are the slopes, then $m_1m_2 = -b^2/a^2$. One pair of conjugate diameters are the diagonals of the rectangle circumscribing the ellipse. The eccentric angles of the ends of two conjugate diameters differ by 90 deg. Thus (Fig. 30), if CQ and CQ' are perpendicular radii in the circle, CP and CP' will be conjugate semi-diameters in the ellipse. A parallelogram formed by tangents drawn parallel to a pair of conjugate diameters has a constant area, = 4ab (Fig. 31). Also, if a',b' are conjugate semi-diameters, and w the angle between them, then $a'^2 + b'^2 = a^2 + b^2$ and $a'b' = ab/\sin w$.

To Construct a Tangent to a Given Ellipse. (1) At a Given Point of Contact, P. Bisect the angle between the focal radii PF and PF' (Fig. 25). (2) From a Given External Point, R. (a) Through R draw any two lines cutting the ellipse, one in A and B, the other in C and D (Fig. 32). Through the point of intersection of AD and BG and the point of intersection of AC and BD, draw a line cutting the ellipse in P and Q. Then P and Q are the required points of contact. (b) With R as a center and radius RF, draw an arc; with F' as center and radius 2a draw an arc, intersecting the first in S; and let SF' meet the curve in T. Then T is the point of contact (Fig. 33).

To Construct an Ellipse, Given a and b. (1) In Fig. 34, with O as center, draw circles with radii a and b (and also a third circle with radius a + b). Let a variable ray through O cut these circles in J, K (and S); through J and K draw parallels to the axes, meeting in P. Then P is a point of the ellipse (and SP is the normal at P).

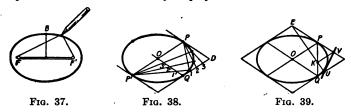

(2) In Fig. 35, let P divide a line AB so that PA = a and PB = b. Then if A and B slide on the axes, P will describe an ellipse.

(3) In Fig. 36, let PBA be a straight line such that PA = a and PB = b. Then if A and B slide on the axes, P will trace an ellipse. (Use a strip of paper, with the points P, B, and A marked on it.)

(4) Find the foci, F and F', by striking an arc of radius a with center at B (Fig. 37). Drive pins at F, F', and B, and adjust a loop of thread around them. Then remove the pin at B, and replace it by a pencil point; by moving the pencil so as to keep the string taut, the complete ellipse can be drawn at one sweep. Or, use a mechanical ellipsograph.

(5) and (6). Apply methods (1) and (2) of the following paragraph to the special case in which OP and OQ are perpendicular semi-axes.

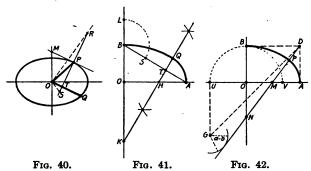

To Construct an Ellipse, Given a Pair of Conjugate Semi-diameters, OP and OQ. (1) Complete the parallelogram, as in Fig. 38. Divide QD and QO into n equal parts, 1, 2, 3, . . . and 1', 2', 3', . . . Connect P with 1, 2, 3, . . . and P' with 1', 2', 3' The points of intersection of corresponding lines will be points of the ellipse.

(2) Take any point K on PQ (Fig. 39). Draw EKU, and draw KV parallel to OP. Then UV will be a tangent. By varying K along PQ as many tangents may be drawn as desired, thus "enveloping" the ellipse.

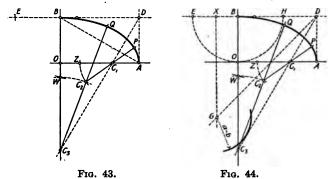

(3) Through P (Fig. 40), draw a perpendicular PT to OQ, and lay off PR = PS = OQ. Then if the line RPT is made to slide with one end on OR and the other on OQ, P will trace the ellipse. Further, the bisectors of the angle ROS show the directions of the principal axes, and OR + OS = 2a and

OR - OS = 2b. Also, if a line through P perpendicular to RS (and therefore tangent to the ellipse at P) meets the minor axis in M, a circle with M as center and MR or MS as radius will cut the major axis in the two foci.

To Construct an Ellipse Approximately by Circular Arcs. [Methods (1) and (2) employ two radii, (3) and (4) employ three radii.] (1) In Fig. 41, lay off OL = OA and BS = BL = a - b. Bisect SA in T, and draw THK perpendicular to BA. Then H is one center, with radius HA, and K is the other center, with radius KB. The junction point Q of the two arcs will fall a little outside the true ellipse.

(2) In Fig. 42, lay off OU = OV = OB = b. Draw UG perpendicular to the axis and DG at 45°. With G as center draw an auxiliary arc with radius

= AV = a - b, and through D draw DMN just touching this arc. Then M is one center (with radius MA) and N is the other center (with radius NB). The junction point P of the two arcs will be a true point of the ellipse. [E. V. Huntington.]

(3) Through D (Fig. 43) draw DC_1C_2 perpendicular to AB. Call $C_1A = r_1$ and $C_2B = r_2$. Lay off BE = BO (=b), and on ED as diameter draw a semicircle cutting the minor axis in W; then $BW = \sqrt{ab} = r_2$. Lay off $AZ = r_3$.

BW. From C_1 with radius $C_1Z(=r_2-r_1)$, and from C_3 with radius C_3W $(=r_3-r_2)$, draw arcs intersecting in C_2 . Draw C_3C_2 extended and C_2C_1 extended. Then draw in the three arcs, with centers at C_1 , C_2 , C_3 and radii r_1 , r_2 , r_3 . Note. Since r_1 and r_3 are the radii of curvature of the ellipse at A and B, this construction gives a curve which is a little too sharp at A and a little too flat at B. A more accurate construction is the following:

(4) In Fig. 44, lay off BE = BH = BO = b. Through the mid-point X of BE draw XG perpendicular to the axis, and through D draw DG at an angle of 45 deg. From G as center draw an auxiliary are with radius = DH (= a - b), and through D draw DC_1C_2 just touching this are. Take C_1A as r_1 and C_2B as r_2 . On DE as diameter draw a semi-circle cutting the minor axis in W, and take $BW (= \sqrt{ab})$ as r_2 . Lay off AZ = BW. From C_1

with radius $C_1Z(=r_2-r_1)$, and from C_3 with radius $C_3W(=r_3-r_2)$, draw arcs intersecting in C_2 . Then C_1 , C_3 , C_3 are the required centers. [E.

V. Huntington.]

Radius of Curvature of Ellipse at Any Point P = (x, y) is $R = a^2b^2(x^2/a^4 + y^2/b^4)^{3/2} = p/\sin^3 v$, where v is the angle which the tangent at P makes with PF or PF'. At end of major axis, $R = b^2/a = MA$; at end of minor axis, $R = a^2/b = NB$ (see Fig. 45). To construct the radius of curvature at any other point P

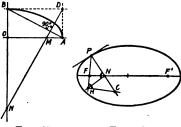

Fig. 45. Fig. 46.

(Fig. 46), draw the normal at P (by bisecting the angle between PF and PF') and let it meet the major axis in N. At N draw a perpendicular to PN meeting PF in H. At H draw a perpendicular to PH meeting PN in C. Then C is the center of curvature for the point P, and a circle about C with radius CP will coincide closely with the ellipse in the neighborhood of P. [Note. If the circle of curvature meets the ellipse in Q, then the tangent at P and the line PQ are equally inclined to the axis.]

THE HYPERBOLA

The hyperbola (see also p. 107) has two foci, F and F', at distances $\pm ae$ from the center, and two directrices, DH and D'H', at distances $\pm a/e$ from

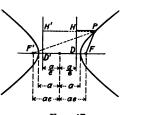

Fig. 47.

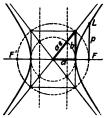

Fig. 48.

the center (Fig. 47). If P is any point of the curve, |PF - PF'| is constant, -2a; and PF/PH (or PF'/PH') is also constant, -e (called the **eccentricity**), where e > 1. Either of these properties may be taken as the definition of the

curve. The curve has two branches which approach more and more nearly two straight lines called the **asymptotes**. Each asymptote makes with the principal axis an angle whose tangent is b/a. The relations between e, a, and b are shown in Fig. 48: $b^2 = a^2(e^2 - 1)$, $ae = \sqrt{a^2 + b^2}$, $e^2 = 1 + (b/a)^2$. The semi-latus rectum, or ordinate at the focus, is $p = a(e^2 - 1) = b^2/a$.

Any section of a right circular cone made by a plane which cuts both nappes of the cone will be a hyperbola. (Compare also Fig. 3, p. 174.)

Equation of the Hyperbola, center as origin:

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$$
, or $y = \pm \frac{b}{a} \sqrt{x^2 - a^2}$.

If P = (x,y) is on the right-hand branch, PF = ex - a, PF' = ex + a. If P is on the left-hand branch, PF = -ex + a, PF' = -ex - a.

Equations of Hyperbola in Parametric Form. (1) $x = a \cosh u$, $y = b \sinh u$. (For tables of hyperbolic functions, see pp. 60 and 61.) Here u may be interpreted as A/a^2 , where A is the area shaded in Fig. 49.

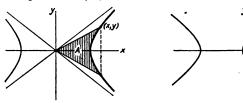

Fig. 49. Fig. 50.

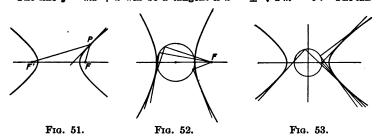

(2) $x = a \sec v$, $y = b \tan v$, where v is an auxiliary angle of no special geometric interest.

Polar Equation, referred to focus as origin, axes as in Fig. 50:

$$r = p/(1 - e \cos \theta).$$

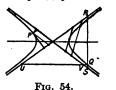

Equation of the Tangent at (x_1,y_1) : $b^2x_1x-a^2y_1y=a^2b^2$.

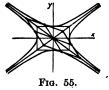

The line y = mx + k will be a tangent if $k = \pm \sqrt{a^2m^2 - b^2}$. The tan-

gent at any point P (Fig. 51), bisects the angle between PF and PF'. The locus of the foot of the perpendicular from the focus on a moving tangent is the circle on the principal axis as diameter (Fig. 52). The locus of the point of intersection of perpendicular tangents is a circle with radius $\sqrt{a^2 - b^2}$, which will be imaginary if b > a (Fig. 53).

Properties of the Asymptotes. (Fig. 54.) If P is any point of the curve, the product of the perpendicular distances from P to the two asymptotes is constant, = $a^2b^2/(a^2 + b^2)$. Also, the product of the oblique distances (the distance to each asymptote being measured parallel to the other) is constant, and equal to $\mathcal{H}(a^2 + b^2)$. If a line cuts the hyperbola and its asymptotes, the parts of the line intercepted between the curve and the asymptotes are equal. The part of a tangent intercepted between the asymptotes is bisected by the point of contact. The triangle bounded by the asymptotes and a variable tangent is of constant area, = ab. If a line through Q perpendicular to the principal axis meets the asymptotes in R and S (see Fig. 54), then $\overline{QR} \times \overline{QS} = b^2$. If a line through Q parallel to the principal axis meets the asymptotes in Q and Q, then Q are Q and Q are Q.

Conjugate Hyperbolas are two hyperbolas having the same asymptotes with semi-axes interchanged (Fig. 55). The equation of the hyperbola conju-

gate to
$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$$
, is $\frac{x^2}{a^2} - \frac{y^2}{b^2} = -1$.

Conjugate Diameters are lines through the center, each of which bisects all the chords parallel to the other—a chord which does not meet the given hyperbola being understood to be terminated by the conjugate hyperbola (Fig. 55). If m_1 and m_2 are the slopes, then $m_1m_2 = b^3/a^2$. Each asymptote, regarded as a diameter, is its own conjugate. If a parallelogram is formed by tangents drawn parallel to a pair of conjugate diameters, its vertices will lie on the asymptotes, and its area will be constant = 4ab. If a', b' are conjugate semi-diameters, and w the angle between them, then $a'^2 - b'^2 = a^2 - b^2$, and $a'b' = ab/\sin w$.

Equilateral Hyperbola (a = b). Equation referred to principal axes (Fig. 56): $x^2 - y^2 = a^2$. Note. p = a. Equation referred to asymptotes as axes (Fig. 57): $xy = a^2/2$. (See also Fig. 3, p. 174.)

Asymptotes are perpendicular. Eccentricity = $\sqrt{2}$. Any diameter is equal in length to its conjugate diameter.

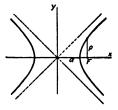

Fig. 57.

To Construct a Tangent at any given point P of a hyperbola. In Fig. 58, draw PA and PB parallel to the asymptotes, and take OS = 2(OA) and OT = 2(OB). Then ST is the tangent at P.

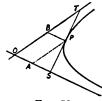

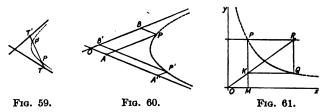

Fig. 58.

To Construct a Hyperbola, given the asymptotes and any point P. (1) In Fig. 59 let TPT' be a variable line through P, and lay off T'P' = TP; then P' is a point of the curve.

(2) In Fig. 60, draw PA and PB parallel to the asymptotes. Lay off OA' = n(OA) and OB' = (1/n)(OB), where n is any number; and through A' and B' draw parallels to the axes; these will meet in a point P' of the curve.

(3) (Fig. 61.) Take any point K in the ordinate PM, and draw OK meeting the line through P parallel to the x-axis in R. Draw a parallel to the x-axis through K and a parallel to the y-axis through R, meeting in Q. Then Q is a point of the curve.

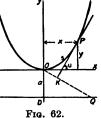

THE CATENARY

The catenary is the curve in which aflexible chain or cord of uniform density will hang when supported by the two ends. Let $w = \frac{1}{2} \left(\frac{1}{2} \right) \left(\frac$

weight of the chain per unit length; T = the tension at any point P; and T_h, T_v = the horizontal and vertical components of T. The horizontal component T_h is the same at all points of the curve.

The length $a = T_h/w$ is called the **parameter** of the catenary, or the distance from the lowest point O to the **directrix** DQ (Fig. 62). When a is very large, the curve is very flat. For methods of finding a in any given case, see problems 1-6 below.

The rectangular **equation**, referred to the lowest point as origin, is y = a [cosh (x/a) - 1]. (For table of hyperbolic functions, see p. 60.) In case of

very flat arcs (a large), $y = \frac{x^2}{2a} + \dots$; $s = x + \frac{x^3}{a^2} + \dots$, approximately,

so that in such a case the catenary closely resembles a parabola.

If the perpendicular from O to the tangent at P meets the directrix in Q, then $DQ = \operatorname{arc} OP = s$ and OQ = y + a. The radius of curvature at P is $R = (y + a)^2/a$, which is equal in length to the portion of the normal intercepted between P and the directrix.

Problems on the Catenary (Fig. 62). When any two of the four quantities x, y, s, T/w are known, the remaining two, and also the parameter a, can be found, as follows:

(1) Given x and y. Compute y/x, and find from Table 1 the value of the auxiliary variable z. Then compute a = x/z, s = a sinh z, and $T = wa \cosh z$. Or, having z, find s/x and wx/T by using Tables 3 and 2 inversely, and hence (since x is known) compute s and T/w without the use of a.

TABLE 3. GIVING z WHEN s/x is Known. Then a = x/z

(4) GIVEN
$$y$$
 AND s . Then $\frac{T}{w} = \frac{s^2}{2y} + \frac{y}{2}$, $x = \left(\frac{s^2}{y} - y\right) \tanh^{-1}\left(\frac{y}{s}\right)$, $a = \frac{s^2}{2y} - \frac{y}{2}$. Or, if y/s is small, $x = s \left[1 - \frac{2}{3}\left(\frac{y}{s}\right)^2 - \frac{2}{15}\left(\frac{y}{s}\right)^4 - \dots\right]$.

(5) GIVEN y AND T/w . Then $a = \frac{T}{w} - y$, $x = \left(\frac{T}{w} - y\right) \cosh^{-1}\frac{T/w}{(T/w) - y}$, $s = \sqrt{2y(T/w) - y^2}$. Or, if $y/(T/w)$ is small, $x = \sqrt{\frac{2yT}{s}} \left[1 - \frac{7}{12}\frac{wy}{T} - \dots\right]$, $\frac{s - x}{s} = \frac{1}{3}\frac{wy}{T}$, approximately,

$$x = \sqrt{\frac{w}{w}} \left[1 - \frac{1}{12} \frac{wy}{T} - \cdots \right], \quad \frac{s}{s} = \frac{1}{3} \frac{s}{T}, \text{ approximate}$$

$$s = \sqrt{\frac{2yT}{w}} \left[1 - \frac{1}{4} \frac{wy}{T} - \frac{1}{32} \left(\frac{wy}{T} \right)^2 - \frac{1}{128} \left(\frac{wy}{T} \right)^3 - \cdots \right].$$

1.10

0.7634

(6) GIVEN s AND
$$T/w$$
. Then $x = \frac{T}{w} \sqrt{1 - \left(\frac{ws}{T}\right)^2} \tanh^{-1}\left(\frac{ws}{T}\right)$,

$$y = \frac{T}{w} - \frac{T}{w} \sqrt{1 - \left(\frac{ws}{T}\right)^2}, \quad a = \frac{T}{w} \sqrt{1 - \left(\frac{ws}{T}\right)^2}. \quad \text{Or, if } ws/T \text{ is small,}$$

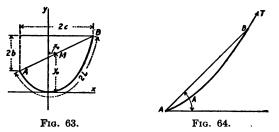

$$x = s \left[1 - \frac{1}{6} \left(\frac{ws}{T}\right)^2 - \frac{11}{120} \left(\frac{ws}{T}\right)^4 - \cdots \right], \quad y = s \left[\frac{1}{2} \left(\frac{ws}{T}\right) + \frac{1}{8} \left(\frac{ws}{T}\right)^3 + \cdots \right]$$

$$a = \frac{T}{w} \left[1 - \frac{1}{2} \left(\frac{ws}{T}\right)^2 - \frac{1}{8} \left(\frac{ws}{T}\right)^4 - \cdots \right].$$

Given the Length 2L of a Chain Supported at Two Points A and B not in the Same Level, to find a. (See Fig. 63; b and c are supposed known.) Let $(\sqrt{L^2-b^2})/c = s/x$; enter Table 3 with this value of s/x, and find the corresponding value of the auxiliary variable z. Then a = c/z.

Note. The co-ordinates of the mid-point M of AB (see Fig. 63) are $x_0 = a \tanh^{-1}(b/L)$, $y_0 = (L/\tanh z) - a$, so that the position of the lowest point is determined.

Correction for Sag in Chaining Uphill (Fig. 64). Let l = length of tape (corrected for stretch and temperature), w = weight per unit length of tape, A = angle between the chord AB and the horizontal.

If the tension P at the upper end is known, compute wl/P and find k from Table 4. If the tension Q at the lower end is known, compute wl/Q and find k from Table 5. In either case, chord AB = l - kl.

OTHER USEFUL CURVES

The Cycloid is traced by a point on the circumference of a circle which rolls without slipping along a straight line. **Equations** of cycloid, in parametric form (axes as in Fig. 65): x = a (rad $u - \sin u$), $y = a(1 - \cos u)$, where a is

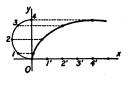

Fig. 66.

the radius of the rolling circle, and rad u is the radian measure of the angle u through which it has rolled. The tangent and normal at any point pass through the highest and lowest points of the corresponding position of the generating circle. The radius of curvature at any point P is $PC = 4a \sin(u/2) = 2\sqrt{2ay}$ = twice the length of the normal, PN. The evolute, or locus of centers of curvature, is an equal cycloid. To construct a cycloid (Fig. 66), divide the semi-circumference of the gen-

eycloid. To construct a cycloid (Fig. 66), divide the semi-circumference of the generating circle into n equal parts (here 4) and lay off these arcs along the base (from O to 4'). Describe arcs with centers at 1', 2', . . . and radii equal to the chords O1, O2, . . ., and sketch the cycloid as a curve tangent to all of these arcs. Or, on horizontal lines through $1, 2, \ldots$ lay off distances equal to O1', O2', etc.; the points

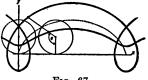

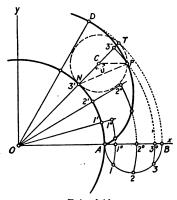

Fig. 67.

tances equal to O1', O2', etc.; the points thus reached will lie on the cycloid.

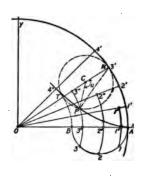

The area of one arch = $3\pi a^2$, length of arc of one arch = 8a. Area bounded by the ordinate of the point P corresponding to any value of u is a^2 (½ rad $u-2\sin u+$ ½ sin 2u) = $\frac{34}{2}ax-\frac{14}{2}y\sqrt{(2a-y)y}$. Length of arc OP=4a $(1-\cos \frac{14}{2}u)=4a-2\sqrt{2a(2a-y)}$.

The Trochoid is a more general curve, traced by any point on a radius of the rolling circle, at distance b from the center (Fig. 67). It is a prolate trochoid if b < a, and a curtate or looped trochoid if b > a. The equations in either case are x = a rad u - b sin u, y = a - b cos u.

The Epicycloid (or Hypocycloid) is a curve generated by a point on the circumference of a circle of radius a which rolls without slipping on the outside (or inside) of a fixed circle of radius c. For the equations, put b = a in the equations of the epi- (or hypo-) trochoid, below. The normal at any point P passes through the point of contact N of the corresponding position of the rolling circle. To construct the curve (Figs. 68 and 69),

Epicycloid. Fig. 68.

Hypocycloid. Fig. 69.

divide the semi-circumference of the rolling circle into n equal parts, by points 1, 2, 3 . . ., and lay off these arcs (A1, A2, A3) along the circumference of the base circle, as $A1', A2', A3', \ldots$. Describe circles with centers at $1', 2', 3', \ldots$ and radii equal to the chords $A1, A2, A3, \ldots$; then the required curve will be tangent to all these circles. Or, with O as center, draw arcs through 1, 2, 3, . . ., meeting the radius OA in 1^0 , 2^0 , 3^0 , . . ., and the radii $O1', O2', O3', \ldots$ in $1'', 2'', 3'', \ldots$; then from $1'', 2'', 3'', \ldots$ is an off arcs equal to 1^01 , 2^02 , 3^03 , . . . respectively; the points thus reached will be points of the curve.

The area $OAP = \frac{a(c \pm a)(c \pm 2a)}{2c}$ (rad $u - \sin u$), where the upper sign applies to the epicycloid, the lower to the hypocycloid, and rad u = the radian measure of the angle u shown in Figs. 68 and 69. Arc $AP = (4 \ a/c)(c \pm a)(1 - \cos \frac{1}{2} u)$; arc $AD = (4a/c)(c \pm a)$. [In Fig. 69, $D = 4^{n}$.]

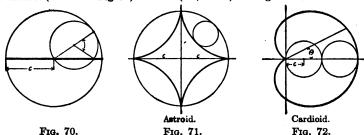

Radius of curvature at any point P is $R = \frac{4a(c \pm a)}{c \pm 2a} \sin \frac{1}{2}u$; at A, R = 0;

at D,
$$R = \frac{4a(c \pm a)}{c \pm 2a}$$
.

Special Cases. If $a = \frac{1}{2}c$, the hypocycloid becomes a straight line, diameter of the fixed circle (Fig. 70). In this case the hypotrochoid traced by any

point rigidly connected with the rolling circle (not necessarily on the circumference) will be an ellipse. If $a = \frac{1}{2}c$, the curve generated will be the four-cusped hypocycloid, or **astroid**, (Fig. 71), whose equation is $x^{\frac{3}{4}} + y^{\frac{3}{4}} = c^{\frac{3}{4}}$. If a = c, the epicycloid is the **cardioid**, whose equation in polar coordinates (axes as in Fig. 72) is $r = 2c(1 + \cos \theta)$. Length of cardioid = 16c.

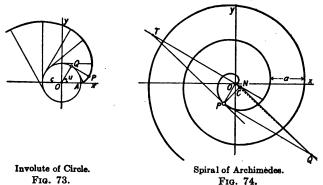

The Epitrochoid (or Hypotrochoid) is a curve traced by any point rigidly attached to a circle of radius a, at distance b from the center, when this circle rolls without slipping on the outside (or inside) of a fixed circle of radius c.

The equations are
$$x = (c \pm a) \cos \left(\frac{a}{c}u\right) \mp b \cos \left[\left(1 \pm \frac{a}{c}\right)u\right]$$
,

$$y = (c \pm a) \sin\left(\frac{a}{c}u\right) - b \sin\left[\left(1 \pm \frac{a}{c}\right)u\right]$$
, where $u =$ the angle which the

moving radius makes with the line of centers; take the upper sign for the epiand the lower for the hypo-trochoid. The curve is called prolate or curtate according as b < a or b > a. When b = a, the special case of the epi- or hypocycloid arises.

The Involute of a Circle is the curve traced by the end of a taut string which is unwound from the circumference of a fixed circle, of radius c. If QP

is the free portion of the string at any instant (Fig. 73), QP will be tangent to the circle at Q, and the length of QP = length of arc QA; hence the construc-

tion of the curve. The equations of the curve in parametric form (axes as in figure) are $x = c(\cos u + \operatorname{rad} u \sin u)$, $y = c(\sin u - \operatorname{rad} u \cos u)$, where rad u is the radian measure of the angle u which OQ makes with the x-axis. Length of arc $AP = \frac{1}{2}c(\operatorname{rad} u)^2$; radius of curvature at P is QP.

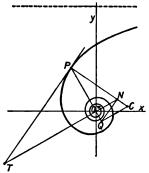

The Spiral of Archimedes (Fig. 74) is traced by a point P which, starting from O, moves with uniform velocity along a ray OP, while the ray itself revolves with uniform angular velocity about O. Polar equation: r = k rad θ , or r = a ($\theta/360^{\circ}$). Here $a = 2\pi k =$ the distance, measured along a radius, from each coil to the next.

In order to construct the curve, draw radii O1, O2, O3, . . . making angles $\frac{1}{n}(360^{\circ})$, $\frac{2}{n}(360^{\circ})$, $\frac{3}{n}(360^{\circ})$, . . . with Ox, and along these radii lay off distances equal to $\frac{1}{n}a$, $\frac{2}{n}a$, $\frac{3}{n}a$, . . .; the points thus reached will lie on the spiral. The figure shows one-half of the curve, corresponding to

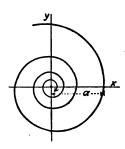

positive values of θ .

Construction for tangent and normal: Let PT and PN be the tangent and normal at any point P, the line TON being perpendicular to OP. Then $OT = r^2/k$, and ON = k, where $k = a/(2\pi)$. Hence the construction.

The radius of curvature at P is $R = (k^2 + r^2)^{\frac{3}{2}}/(2k^2 + r^2)$. To construct the center of curvature, C, draw NQ perpendicular to PN and PQ perpendicular to OP; then OQ will meet PN in C. Length of arc $OP = \frac{1}{2}k$ [rad $\theta \sqrt{1 + (\text{rad }\theta)^2 + \sinh^{-1}(\text{rad }\theta)}$]. After many windings, are $OP = \frac{1}{2}r^2/k$, approximately.

Hyperbolic Spiral. Fig. 75.

Logarithmic Spiral. Fig. 76.

The Hyperbolic Spiral is the curve whose polar equation is $r=a/\text{rad }\theta$. To construct the curve, take a series of points along Ox (Fig. 75); through each of these points, with center at O, draw an arc extending into the upper half of the plane; and along each of these arcs lay off a length =a. The points thus reached will lie on the curve. A line parallel to the x-axis, at distance a, is an asymptote of the curve. The curve winds around and around the point O without ever reaching it (asymptotic point). The figure shows one-half of the curve, corresponding to positive values of θ . If PT and PN are the tangent and normal at any point P, the line TON being perpendicular to OP.

when OT = a, and $ON = r^2/a$. Hence a construction for the tangent and normal. Radius of curvature at P is $R = r/\sin^2 v$, where v = angle between OP and the tangent at P. Construction: At N draw a perpendicular to PN, meeting PO in Q; at Q draw a perpendicular to PQ, meeting PN in C; then C is the center of curvature for the point P.

The Logarithmic Spiral (Fig. 76), is a curve which cuts the radii from O at a constant angle v, whose cotangent is m. Polar equation: $r = ae^{m \operatorname{rad} \theta}$. Here a is the value of r when $\theta = 0$. For large negative values of θ , the curve winds around O as an asymptotic point. If PT and PN are the tangent and normal at P, the line TON being perpendicular to OP (not shown in fig.), then ON = rm, and $PN = r\sqrt{1 + m^2} = r/\sin v$. Radius of curvature at

P is PN. The evolute of the spiral is an equal spiral whose axis makes an angle $\frac{1}{2}\pi - (\log_{\theta} m)/m$ with the axis of the given spiral. Area swept out by the radius r from r = 0 (where $\theta = -\infty$) to r = r, is $A = r^2/(4m) = \text{half}$ the triangle OPT. Length of arc from O to $P = s = r/\cos v = PT$.

Tractrix.
Fig. 77.

The Tractrix, or Schiele's Anti-friction Curve (Fig. 77), is a curve such that the portion PT of the tangent between the point of contact and the x-axis is

constant = a. Its equation is $x = \pm a \left[\cosh^{-1} \frac{a}{y} - \sqrt{1 - \left(\frac{y}{a}\right)^2} \right]$, or, in

parametric form, $x = \pm a [t - \tanh t]$, $y = a/\cosh t$. (For tables of hyperbolic functions, see p. 60.) The x-axis is an asymptote of the curve. Length of arc $BP = a \log_a (a/y)$. The evolute (locus of centers of curvature) is the catenary whose lowest point is at B, and whose directrix is Ox.

The Cissoid (Fig. 78) is the locus of a point P such that OP, laid off on a variable ray from O, is equal to BD, the portion of the ray lying between a fixed circle through O and a fixed tangent at the point A opposite O. If a is the radius of the circle, the polar equation is $r = 2a \sin^2 \theta / \cos \theta$. Rectangular equation, $y^2(2a - x) = x^2$.

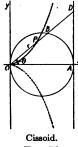

Fig. 78.

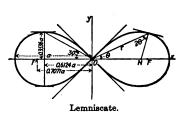

Fig. 79.

The Lemniscate (Fig. 79) is the locus of a point P the product of whose distances from two fixed points F, F' is constant, equal to $\frac{1}{2}a^2$. The distance $FF' = a\sqrt{2}$. Polar equation is $r = a\sqrt{\cos 2\theta}$. Angle between OP and the ramal at P is 2θ . The two branches of the curve cross at right angles at O.

Maximum y occurs when $\theta = 30^{\circ}$ and $r = a/\sqrt{2}$, and is equal to 14 th Area of one loop $= a^{2}/2$.

The Heliz (Fig. 80) is the curve of a screw thread on a cylinder of radius r.

The curve crosses the elements of the cylinder at a constant angle, v. The pitch, h, is the distance between two coils of the helix, measured along an element of the cylinder; hence $h=2\pi r$ tan v. Length of one coil = $\sqrt{(2\pi r)^2 + h^2}$ = $2\pi r/\cos v$. To construct the projection of a helix on a plane containing the axis of the cylinder, draw a rectangle, breadth 2r and height h, to represent the plane, with a semicircle below it, as in the figure, to represent the base of the cylinder. Divide h into equal parts (here 8), numbered from 1 to 8; think of the circumterence as also divided into 8 equal parts, represented on the semicircle by numbers from 1' to 4' and back again from 4' to 8'. Then the point of intersection of a horizontal line through $1, 2, \ldots$ with a vertical line through $1', 2', \ldots$ will be a point of the required projection. If the cylinder is

Heliz. Fig. 80.

rolled out on a plane, the development of the helix will be a straight line, with alope equal to tan v.

DIFFERENTIAL AND INTEGRAL CALCULUS

DERIVATIVES AND DIFFERENTIALS

Derivatives and Differentials. A function of a single variable x may be denoted by f(x), F(x), etc. The value of the function when x has the value x_0 is then denoted by $f(x_0)$, $F(x_0)$, etc. The derivative of a function y = f(x)may be denoted by f'(x), or by dy/dx. The value of the derivative at a given point $x = x_0$ is the rate of change of the function at that point; or, if the function is represented by a curve in the usual way (Fig. 1), the value of the derivative at any point shows the slope of the curve (that is, the slope of the tangent to the curve) at that point

(positive if the tangent points upward, and negative

if it points downward, moving to the right).

The increment, Δy (read: "delta y"), in y is the change produced in y by increasing x from x_0 to x_0 + Δx ; that is, $\Delta y = f(x_0 + \Delta x) - f(x_0)$. The differ**ential**, dy, of y is the value which Δy would have if the curve coincided with its tangent. (The differential, dx, of x is the same as Δx when x is the independent variable.) Note that the derivative depends only on the value of x_0 , while Δy and dy depend not only on x_0 but also on the value of Δx . The ratio

y = f(x)Fig. 1.

 $\Delta y/\Delta x$ represents the slope of the secant, and dy/dx the slope of the tangent (see Fig. 1). If Δx is made to approach zero, the secant approaches the tangent as a limiting position, so that the derivative = f'(x) =

$$\frac{dy}{dx} = \lim_{\Delta x = 0} \left[\frac{\Delta y}{\Delta x} \right] = \lim_{\Delta x = 0} \left[\frac{f(x_0 + \Delta x) - f(x_0)}{\Delta x} \right]. \text{ Also, } dy = f'(x) dx.$$

The symbol "lim" in connection with $\Delta x \doteq 0$ means "the limit, as Δx approaches 0, of ..." [A constant c is said to be the **limit** of a variable u if, whenever any quantity m has been assigned, there is a stage in the variationprocess beyond which |c-u| is always less than m; or, briefly, c is the limit of u if the difference between c and u can be made to become and remain as small as we please.]

To find the derivative of a given function at a given point: (1) If the function is given only by a curve, measure graphically the slope of the tangent at the point in question; (2) if the function is given by a mathematical expression, use the following rules for differentiation. These rules give, directly, the differential, dy, in terms of dx; to find the derivative, dy/dx, divide through by dx.

Rules for Differentiation. (Here u, v, w, ... represent any functions of a variable x, or may themselves be independent variables. a is a constant which does not change in value in the same discussion; e = 2.71828.)

1.
$$d(a + u) = du$$
. 2. $d(au) = adu$.

3.
$$d(u + v + w + ...) = du + dv + dw + ...$$

 $4. \ d(uv) = udv + vdu.$

5.
$$d(uvv...) = (uvv...) \left(\frac{du}{u} + \frac{dv}{v} + \frac{dw}{w} + ... \right)$$

$$6. \ d\frac{u}{v} = \frac{vdu - udv}{v^2}$$

7.
$$d(u^m) = mu^{m-1}du$$
 when m is not = -1.

Thus, $d(u^2) = 2udu$; $d(u^3) = 3u^2du$; etc.

8.
$$d\sqrt{u} = \frac{du}{2\sqrt{u}}$$

$$10. \ d(e^u) = e^u du.$$

12.
$$d \log_{\bullet} u = \frac{du}{u}$$

14.
$$d \sin u = \cos u du$$
.

$$16. \ d\cos u = -\sin u \, du.$$

18.
$$d \tan u = \sec^2 u du$$
.

$$20. \ d \sin^{-1} u = \frac{du}{\sqrt{1 - u^2}}.$$

22.
$$d \cos^{-1} u = -\frac{du}{\sqrt{1-u^2}}$$

24.
$$d \tan^{-1} u = \frac{du}{1 + u^2}$$

26.
$$d \log_a \sin u = \cot u du$$
.

30.
$$d \sinh u = \cosh u \, du$$
.

32.
$$d \cosh u = \sinh u du$$
.
34. $d \tanh u = \operatorname{sech}^2 u du$.

36.
$$d \sinh^{-1} u = \frac{du}{\sqrt{u^2 + 1}}$$

38.
$$d \cosh^{-1} u = \frac{du}{\sqrt{u^2 - 1}}$$

40.
$$d \tanh^{-1} u = \frac{du}{1 - u^2}$$

$$9. \ d\left(\frac{1}{u}\right) = -\frac{du}{u^2}.$$

11.
$$d(a^u) = (\log_a a)a^u du.$$

13.
$$d \log_{10} u = (\log_{10} e) \frac{du}{u} = (0.4343...) \frac{du}{u}$$

15.
$$d \csc u = -\cot u \csc u du$$
.

17.
$$d \sec u = \tan u \sec u du$$
.

19.
$$d \cot u = -\csc^2 u du$$
.

21.
$$d \csc^{-1} u = -\frac{du}{u\sqrt{u^2 - 1}}$$

23.
$$d \sec^{-1} u = \frac{du}{u\sqrt{u^2 - 1}}$$

25.
$$d \cot^{-1} u = -\frac{du}{1+u^2}$$

27.
$$d \log_a \tan u = \frac{2du}{\sin 2u}$$

28.
$$d \log_s \cos u = -\tan u \, du$$
. 29. $d \log_s \cot u = -\frac{2du}{\sin 2u}$

31.
$$d \operatorname{csch} u = - \operatorname{csch} u \operatorname{coth} u du$$
.

33.
$$d \operatorname{sech} u = - \operatorname{sech} u \tanh u du$$
.

35.
$$d \coth u = - \operatorname{qsch}^2 u \, du$$
.

$$37. d \operatorname{csch}^{-1} u = -\frac{du}{u\sqrt{u^2 + 1}}$$

37.
$$d \operatorname{csch}^{-1} u = -\frac{du}{u\sqrt{u^2 + 1}}$$

39. $d \operatorname{sech}^{-1} u = -\frac{du}{u\sqrt{1 - u^2}}$

41.
$$d \coth^{-1} u = \frac{du}{1 - u^2}$$

$$1 - u^{2}$$

$$42. \ d(u^{v}) = (u^{v-1})(u \log_{\bullet} u \ dv + v \ du).$$

Derivatives of Higher Orders. The derivative of the derivative is called the second derivative; the derivative of this, the third derivative; and so on. Notation: if y = f(x),

$$f'(x) = D_x y = \frac{dy}{dx}; \quad f''(x) = D_x^2 y = \frac{d^2 y}{dx^2}; \quad f'''(x) = D_x^2 y = \frac{d^2 y}{dx^2}; \quad \text{etc.}$$

NOTE. If the notation d^2y/dx^2 is used, this must not be treated as a fraction, like dy/ds but as an inseperable symbol, made up of a symbol of operation, d^2/dx^2 , and an operand y

The geometric meaning of the second derivative is this: if the original function y = f(x) is represented by a curve in the usual way, then at any point where f''(x) is positive, the curve is concave upward, and at any point where f''(x) is negative, the curve is concave downward (Fig. 2). When f''(x) = 0, the curve usually has a **point of** inflection.

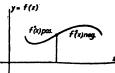

Fig. 2.

Differentials of Higher Orders. The differential of the differential is called the second differential; the differential of this, the third differential; etc. These quantities are of little importance except in the case where dx = a constant. In this case

$$dy = f'(x)dx;$$
 $d^2y = f''(x)\cdot(dx)^2;$ $d^3y = f'''(x)\cdot(dx)^3;$. . .

The first, second, third, etc., differentials are close approximations to the first, second, third, etc., differences (p. 115), and are therefore sometimes useful in constructing tables. Thus, denoting the first, second, third, etc., differences by D', D'', D''', etc., and, assuming always that dx = a constant,

Functions of Two or More Variables may be denoted by $f(x, y, \dots)$, $F(x, y, \ldots)$, etc. The derivative of such a function $u = f(x, y, \ldots)$ formed on the assumption that x is the only variable (y, \ldots, y) . . being regarded for the moment as constants) is called the partial derivative of u with respect to **x**, and is denoted by $f_x(x,y)$, or $D_x u$, or $\frac{d_x u}{dx}$, or $\frac{\partial u}{\partial x}$. Similarly, the partial

derivative of
$$u$$
 with respect to y is $f_y(x,y)$, or D_yu , or $\frac{d_yu}{dy}$, or $\frac{\partial u}{\partial y}$.

NOTE. In the third notation, d_xu denotes the differential of u formed on the assumption that x is the only variable. If the fourth notation, $\partial u/\partial x$, is used, this must not be treated as a fraction like du/dx; the $\partial/\partial x$ is a symbol of operation, operating on u, and the " ∂x " must not be separated.

Partial derivatives of the second of the second $D_x(D_yu)$, D_y^2u , or by $\frac{\partial^2 u}{\partial x^2}$, $\frac{\partial^2 u}{\partial x \partial y}$, $\frac{\partial^2 u}{\partial y^2}$, the last symbols being "inseparable." Partial derivatives of the second order are denoted by f_{xx} , f_{xy} , f_{yy} , or by D_x^2u , Similarly for higher derivatives. Note that $f_{xy} = f_{yx}$.

If increments Δx , Δy , (or dx, dy) are assigned to the independent variables x, y, the increment, Δu , produced in u = f(x,y) is

$$\Delta u = f(x + \Delta x, y + \Delta y) - f(x,y);$$

while the differential, du, that is, the value which Δu would have if the partial derivatives of u with respect to x and y were constant, is given by

$$du = (f_x) \cdot dx + (f_y) \cdot dy.$$

Here the coefficients of dx and dy are the values of the partial derivatives of uat the point in question.

If x and y are functions of a third variable t, then the equation

$$\frac{du}{dt} = (f_x) \frac{dx}{dt} + (f_y) \frac{dy}{dt}$$

expresses the rate of change of u with respect to t, in terms of the separate rates of change of x and y with respect to t.

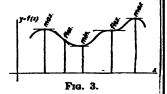

For the graphical representation of u = f(x,y), see p. 178.

Implicit Functions. If f(x,y) = 0, either of the variables x and y is said to be an implicit function of the other. To find dy/dx, either (1) solve for y in terms of x, and then find dy/dx directly; or (2) differentiate the equation through as it stands, remembering that both x and y are variables, and then divide by dx; or (3) use the formula $dy/dx = -(f_x/f_y)$, where f_x and f_y are the partial derivatives of f(x,y) at the point in question.

MAXIMA AND MINIMA

A Function of One Variable, as y = f(x), is said to have a **maximum** at a point $x = x_0$, if at that point the slope of the curve is zero and the concavity downward (see Fig. 3); a sufficient condition for a maximum is $f'(x_0) = 0$ and $f''(x_0)$ negative. Similarly, f(x) has a minimum if the slope is zero and the concavity upward; a sufficient condition for a minimum is $f'(x_0) = 0$ and

 $f''(x_0)$ positive. If $f'(x_0) = 0$ and $f''(x_0) = 0$ and $f'''(x_0) \neq 0$, the point x_0 will be a point of inflection. If $f'(x_0) = 0$ and $f''(x_0) = 0$, the point x_0 will be a maximum if $f'''(x_0) < 0$, and a minimum if $f''''(x_0) > 0$. It is usually sufficient, however, in any practical case, to find the values of x which make f'(x) = 0, and then decide, from a general knowledge of the curve, which of these values (if any) give

maxima or minima, without investigating the higher derivatives.

A Function of Two Variables, as u = f(x,y), will have a **maximum** at a point (x_0,y_0) if at that point $f_x = 0$, $f_y = 0$, and $f_{xx} < 0$, $f_{yy} < 0$; and a **minimum** if at that point $f_x = 0$, $f_y = 0$, and $f_{xx} > 0$, $f_{yy} < 0$; provided, in each case, $(f_{xx})(f_{yy}) - (f_{xy})^2$ is positive. If $f_x = 0$ and $f_y = 0$, and f_{xx} and f_{yy} have opposite signs, the point (x_0,y_0) will be a "saddle point" of the surface representing the function (p. 178).

EXPANSION IN SERIES

The range of values of x for which each of the series is convergent is stated at the right of the series.

Arithmetical and Geometrical Series, and the Binomial Theorem. See p. 114.

Exponential and Logarithmic Series.

$$e^{x} = 1 + \frac{x}{1!} + \frac{x^{2}}{2!} + \frac{x^{3}}{3!} + \frac{x^{4}}{4!} + \dots; \qquad -\infty < x < +\infty,$$

$$a^{x} = e^{mx} = 1 + \frac{m}{1!} x + \frac{m^{2}}{2!} x^{2} + \frac{m^{3}}{3!} x^{3} + \dots; \quad a > 0, \quad -\infty < x < +\infty,$$

$$\text{where } m = \log_{x}^{3} a = (2.3026)(\log_{10} a).$$

$$\log_{x} (1 + x) = x - \frac{x^{2}}{2} + \frac{x^{3}}{3} - \frac{x^{4}}{4} + \frac{x^{5}}{5} - \dots; \qquad -1 < x < +1.$$

$$\log_{x} (1 - x) = -x - \frac{x^{2}}{2} - \frac{x^{3}}{3} - \frac{x^{4}}{4} - \frac{x^{5}}{5} - \dots; \qquad -1 < x < +1.$$

$$\log_{x} \left(\frac{1 + x}{1 - x}\right) = 2\left(x + \frac{x^{3}}{3} + \frac{x^{5}}{5} + \frac{x^{7}}{7} + \dots\right); \qquad -1 < x < +1.$$

$$\log_{x} \left(\frac{x + 1}{x - 1}\right) = 2\left(\frac{1}{x} + \frac{1}{3x^{3}} + \frac{1}{5x^{5}} + \frac{1}{7x^{7}} + \dots\right); \qquad x < -1 \text{ or } +1 < x.$$

$$\log_{x} x = 2\left[\frac{x - 1}{x + 1} + \frac{1}{3}\left(\frac{x - 1}{x + 1}\right)^{3} + \frac{1}{5}\left(\frac{x - 1}{x + 1}\right)^{5} + \dots\right]; \qquad 0 < x < \infty.$$

$$\log_{x} (a + x) = \log_{x} a + 2\left[\frac{x}{2a + x} + \frac{1}{3}\left(\frac{x}{2a + x}\right)^{3} + \frac{1}{5}\left(\frac{x}{2a + x}\right)^{5} + \dots\right];$$

$$\begin{cases} 0 < a < + \infty \\ -a < x < + \infty \end{cases}$$

Series for the Trigonometric Functions. In the following formulæ, all angles must be expressed in radians. If D = the number of degrees in the angle, and x = its radian measure, then x = 0.017453 D.

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots; \qquad -\infty < x < +\infty.$$

$$\cos x = 1 - \frac{x^3}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \frac{x^8}{8!} - \dots; \qquad -\infty < x < +\infty.$$

$$\tan x = x + \frac{x^3}{3} + \frac{2x^5}{15} + \frac{17x^7}{315} + \frac{62x^9}{2835} + \dots; \qquad -\pi/2 < x < +\pi/2.$$

$$\cot x = \frac{1}{x} - \frac{x}{3} - \frac{x^8}{45} - \frac{2x^5}{045} - \frac{x^7}{4725} - \dots; \qquad -\pi < x < +\pi.$$

$$\sin^{-1} y = y + \frac{y^3}{6} + \frac{3y^5}{40} + \frac{5y^7}{112} + \dots;$$
 $-1 \le y \le +1.$

$$\tan^{-1} y = y - \frac{y^3}{3} + \frac{y^5}{5} - \frac{y^7}{7} + \dots;$$
 $-1 \le y \le +1.$

 $\cos^{-1} y = \frac{1}{2}\pi - \sin^{-1} y;$ $\cot^{-1} y = \frac{1}{2}\pi - \tan^{-1} y.$

Series for the Hyperbolic Functions (x a pure number).

$$\sinh x = x + \frac{x^3}{3!} + \frac{x^6}{5!} + \frac{x^7}{7!} + \dots; \qquad -\infty < x < \infty.$$

$$\cosh x = 1 + \frac{x^2}{2!} + \frac{x^4}{4!} + \frac{x^6}{6!} + \dots; \qquad -\infty < x < \infty.$$

$$\sinh^{-1} y = y - \frac{y^3}{6} + \frac{3y^5}{40} - \frac{5y^7}{112} + \dots; \qquad -1 < y < +1.$$

$$\tanh^{-1} y = y + \frac{y^3}{2} + \frac{y^5}{5!} + \frac{y^7}{7!} + \dots; \qquad -1 < y < +1.$$

General Formulæ of Maclaurin and Taylor. If f(x) and all its derivatives are continuous in the neighborhood of the point x = 0 (or x = a), then, for any value of x in this neighborhood, the function f(x) may be expressed as a power series arranged according to ascending powers of x (or of x = a), as follows:

(1)
$$f(x) = f(0) + \frac{f''(0)}{1!}x + \frac{f'''(0)}{2!}x^2 + \frac{f''''(0)}{3!}x^3 + \dots$$

 $+ \frac{f^{(n-1)}(0)}{(n-1)!}x^{n-1} + (P_n)x^n.$ (Maclaurin.)
(2) $f(x) = f(a) + \frac{f'(a)}{1!}(x-a) + \frac{f'''(a)}{2!}(x-a)^2 + \frac{f''''(a)}{3!}(x-a)^3 + \dots$
 $+ \frac{f^{(n-1)}(a)}{(n-1)!}(x-a)^{n-1} + (Q_n)(x-a)^n.$ (Taylor.)

Here $(P_n)x^n$, or $(Q_n)(x-a)^n$, is called the **remainder term**; the values of the coefficients P_n and Q_n may be expressed as follows: $P_n = \{f^{(n)}(sx)\}/n! = \{(1-t)^{n-1} f^{(n)}(tx)\}/(n-1)!$ $Q_n = \{f^{(n)}[a+s(x-a)]\}/n! = \{(1-t)^{n-1} f^{(n)}[a+t(x-a)]\}/(n-1)!$

 $Q_n = \{f^{(n)}[a + s(x - a)]\}/n! = \{(1 - t)^{n-1}f^{(n)}[a + t(x - a)]\}/(n - 1)!$ where s and t are certain unknown numbers between 0 and 1; the s-form is due to Lagrange, the t-form to Cauchy.

The error due to neglecting the remainder term is less than $(\overline{P}_n)x^n$, or 11

 $(\overline{Q}_n)(x-a)^n$, where \overline{P}_n , or \overline{Q}_n , is the largest value taken on by P_n , or Q_n , when s or t ranges from 0 to 1. If this error, which depends on both n and x, approaches 0 as n increases (for any given value of x), then the general-expression-with-remainder becomes (for that value of x) a convergent infinite series.

The sum of the first few terms of Maclaurin's series gives a good approximation to f(x) for values of x near x = 0; Taylor's series gives a similar approximation for values near x = a.

Fourier's Series. Let f(x) be a function which is finite in the interval from x = -c to x = +c and has only a finite number of discontinuities in that interval (see note below), and only a finite number of maxima and minima. Then, for any value of x between -c and c,

$$f(x) = \frac{1}{2} a_0 + a_1 \cos \frac{\pi x}{c} + a_2 \cos \frac{2\pi x}{c} + a_3 \cos \frac{3\pi x}{c} + \dots$$

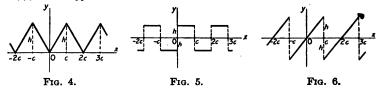

$$+ b_1 \sin \frac{\pi x}{c} + b_2 \sin \frac{2\pi x}{c} + b_3 \sin \frac{3\pi x}{c} + \dots$$

where the constant coefficients are determined as follows:

$$a_n = \frac{1}{c} \int_{-c}^{c} f(t) \cos \frac{n\pi t}{c} dt, \quad b_n = \frac{1}{c} \int_{-c}^{c} f(t) \sin \frac{n\pi t}{c} dt.$$

In case the curve y = f(x) is symmetrical with respect to the origin, the a's are all zero, and the series is a sine series. In case the curve is symmetrical with respect to the y-axis, the b's are all zero, and a cosine series results. (In this case, the series will be valid not only for values of x between -c and c, but also for x = -c and x = c.) A Fourier's series can be integrated term by term; but the result of differentiating term by term will in general not be a convergent series.

NOTE. If $x = x_0$ is a point of discontinuity, $f(x_0)$ is to be defined as $\frac{1}{2}[f_1(x_0) + f_2(x_0)]$, where $f_1(x_0)$ is the limit of f(x) when x approaches x_0 from below, and $f_2(x_0)$ is the limit of f(x) when x approaches x_0 from above.

Examples of Fourier's Series.

1. If y = f(x) is the curve in Fig. 4,

$$y = \frac{h}{2} - \frac{4h}{\pi^2} \left(\cos \frac{\pi x}{c} + \frac{1}{9} \cos \frac{3\pi x}{c} + \frac{1}{25} \cos \frac{5\pi x}{c} + \dots \right)$$

2. If y = f(x) is the curve in Fig. 5,

$$y = \frac{4h}{\pi} \left(\sin \frac{\pi x}{c} + \frac{1}{3} \sin \frac{3\pi x}{c} + \frac{1}{5} \sin \frac{5\pi x}{c} + \dots \right)$$

3. If y = f(x) is the curve in Fig. 6,

$$y = \frac{2h}{\pi} \left(\sin \frac{\pi x}{c} - \frac{1}{2} \sin \frac{2\pi x}{c} + \frac{1}{3} \sin \frac{3\pi x}{c} - \dots \right)$$

INDETERMINATE FORMS

In the following paragraphs, f(x), g(x) denote functions which approach 0; F(x), G(x) functions which increase indefinitely; and U(x) a function which approaches 1; when x approaches a definite quantity a. The problem in each case is to find the limit approached by certain combinations of these functions when x approaches a. The symbol \doteq is to be read "approaches."

Case 1. " $\frac{0}{0}$ " To find the limit of f(x)/g(x) when f(x) = 0 and g(x) = 0, use the theorem that $\lim_{x \to 0} \frac{f'(x)}{g(x)} = \lim_{x \to 0} \frac{f'(x)}{g'(x)}$, where f'(x) and g'(x) are the derivatives of f(x) and g(x). This second limit may be easier to find than the first. If f'(x) = 0 and g'(x) = 0, apply the same theorem a second time: $\lim_{x \to 0} \frac{f'(x)}{g'(x)} = \lim_{x \to 0} \frac{f''(x)}{g''(x)}$; and so on.

Case 2. " $\frac{\infty}{\infty}$ " If $F(x) \doteq \infty$ and $G(x) \doteq \infty$, then $\lim_{x \to \infty} \frac{F'(x)}{G'(x)} = \lim_{x \to \infty} \frac{F'(x)}{G'(x)}$, precisely as in Case 1.

Case 3. " $0 \cdot \infty$." To find the limit of $f(x) \cdot F(x)$ when $f(x) \doteq 0$ and $F(x) \doteq \infty$, write $\lim_{x \to \infty} [f(x) \cdot F(x)] = \lim_{x \to \infty} \frac{f(x)}{1/F(x)}$, or $\lim_{x \to \infty} \frac{F(x)}{1/f(x)}$; then proceed as in Case 1 or Case 2.

Case 4. "00"." If $f(x) \doteq 0$ and $g(x) \doteq 0$, find $\lim_{x \to 0} [f(x)]^{g(x)}$ as follows: let $y = [f(x)]^{g(x)}$, and take the logarithm of both sides thus:

$$\log_{\bullet} y = g(x) \log_{\bullet} f(x);$$

next, find $\lim [g(x) \log_e f(x)]_{,} = m$, by Case 3; then $\lim y = e^m$.

Case 5. "1°." If $U(x) \doteq 1$ and $F(x) \doteq \infty$, find $\lim_{x \to \infty} [U(x)]^{F(x)}$ as follows: let $y = [U(x)]^{F(x)}$, and take the logarithm of both sides, as in Case 4.

Case 6. " ∞ 6." If $F(x) \doteq \infty$ and $f(x) \doteq 0$, find $\lim_{x \to \infty} [F(x)]^{f(x)}$ as follows: let $y = [F(x)]^{f(x)}$, and take the logarithm of both sides, as in Case 4. Case 7. " $\infty - \infty$." If $F(x) \doteq \infty$ and $G(x) \doteq \infty$, write $\lim_{x \to \infty} [F(x) - G(x)]$

 $= \lim \frac{\frac{1}{G(x)} - \frac{1}{F(x)}}{\frac{1}{G(x)}}; \text{ then proceed as in Case 1.} \quad \text{Sometimes it is shorter to ex-}$

 $F(x) \cdot G(x)$ pand the functions in series. It should be carefully noticed that expressions like 0/0, ∞/∞ , etc., do not represent mathematical quantities.

CURVATURE

The radius of curvature R of a plane curve at any point P (Fig. 7) is the distance, measured along the normal, on the concave side of the curve, to the center of curvature, C, this point being the limiting position of the point of intersection of the normals at P and a neighboring point Q, as Q is made to approach P along the curve. If the equation of the curve is y = f(x),

$$R = \frac{ds}{du} = \frac{[1 + (y')^2]^{\frac{3}{2}}}{y''}$$

Fig. 7.

where $ds = \sqrt{dx^2 + dy^2}$ = the differential of arc, $u = \tan^{-1} [f'(x)]$ = the angle which the tangent at P makes with the x-axis, and y' = f'(x) and y'' = f''(x) are the first and second derivatives of f(x) at the point P. Note that $dx = ds \cos u$ and $dy = ds \sin u$. The curvature, K, at the point P, is K = 1/R = du/ds; that is, the curvature is the rate at which the angle u is changing with respect to the length of arc s. If the slope of the curve is small, $K \approx f''(x)$.

If the equation of the curve in polar co-ordinates is $r = f(\theta)$, where r = radim vector and $\theta = \text{polar}$ angle, then

$$R = \frac{[r^2 + (r')^2]^{\frac{3}{2}}}{r^2 - rr'' + 2(r')^2},$$

where $r' = f'(\theta)$ and $r'' = f''(\theta)$.

The evolute of a curve is the locus of its centers of curvature. If one curve is the evolute of another, the second is called the involute of the first.

INDEFINITE INTEGRALS

An integral of f(x)dx is any function whose differential is f(x)dx, and is denoted by f'(x)dx. All the integrals of f(x)dx are included in the expression f'(x)dx + C, where f'(x)dx is any particular integral, and C is arbitrary constant. The process of finding (when possible) an integral of a given function consists in recognising by inspection a function which, when differentiated, will produce the given function; or in transforming the given function into a form in which such recognition is easy. The most common integrable forms are collected in the following brief table; for a more extended list, see B. O. Peirce's "Table of Integrals" (Ginn & Co.).

GENERAL FORMULÆ

1.
$$\int adu = a \int du = au + C \qquad 2. \int (u + v)dx = \int udx + \int vdx$$

3.
$$\int u dv = uv - \int v du$$
 4.
$$\int f(x) dx = \int f[F(y)]F'(y) dy, x = F(y)$$

5.
$$\int dy \int f(x,y) dx = \int dx \int f(x,y) dy.$$

FUNDAMENTAL INTEGRALS

6.
$$\int x^n dx = \frac{x^{n+1}}{n+1} + C$$
; when $n \neq -1$

7.
$$\int \frac{dx}{x} = \log_e x + C = \log_e cx$$
 8.
$$\int e^x dx = e^x + C$$

9.
$$\int \sin x dx = -\cos x + C$$
 10.
$$\int \cos x dx = \sin x + C$$

11.
$$\int \frac{dx}{\sin^2 x} = -\cot x + C$$
 12.
$$\int \frac{dx}{\cos^2 x} = \tan x + C$$

13.
$$\int \frac{dx}{\sqrt{1-x^2}} = \sin^{-1}x + C = -\cos^{-1}x + c$$

14.
$$\int \frac{dx}{1+x^2} = \tan^{-1}x + C = -\cot^{-1}x + c$$

RATIONAL FUNCTIONS

15.
$$\int (a + bx)^n dx = \frac{(a + bx)^{n+1}}{(n+1)b} + C$$

16.
$$\int \frac{dx}{a + bx} = \frac{1}{b} \log_{e} (a + bx) + C = \frac{1}{b} \log_{e} c(a + bx)$$
17.
$$\int \frac{1}{x^{3}} dx = -\frac{1}{x} + C$$
18.
$$\int \frac{dx}{(a + bx)^{2}} = -\frac{1}{b(a + bx)} + C$$
19.
$$\int \frac{dx}{1 - x^{2}} = \frac{1}{24} \log_{e} \frac{1 + x}{1 - x} + C = \tanh^{-1} x + C, \qquad \text{when } x < 1$$
20.
$$\int \frac{dx}{x^{3} - 1} = \frac{1}{24} \log_{e} \frac{x - 1}{x + 1} + C = -\coth^{-1} x + C, \qquad \text{when } x > 1$$
21.
$$\int \frac{dx}{a + bx^{2}} = \frac{1}{2\sqrt{ab}} \log_{e} \frac{\sqrt{ab} + bx}{\sqrt{ab} - bx} + C$$
22.
$$\int \frac{dx}{a - bx^{2}} = \frac{1}{2\sqrt{ab}} \log_{e} \frac{\sqrt{ab} + bx}{\sqrt{ab} - bx} + C$$

$$= \frac{1}{2\sqrt{b^{3} - ac}} \tan^{-1} \left(\sqrt{\frac{b}{a}} x \right) + C$$
23.
$$\int \frac{dx}{a + 2bx + cx^{2}} = \frac{1}{\sqrt{ac - b^{2}}} \tan^{-1} \frac{b + cx}{\sqrt{b^{3} - ac} + b + cx} + C$$

$$= -\frac{1}{2\sqrt{b^{3} - ac}} \log_{e} \frac{\sqrt{b^{3} - ac} - b - cx}{\sqrt{b^{3} - ac} + b + cx} + C$$

$$= -\frac{1}{\sqrt{b^{3} - ac}} \tan^{-1} \frac{b + cx}{\sqrt{b^{3} - ac}} + C,$$
24.
$$\int \frac{dx}{a + 2bx + cx^{2}} = -\frac{1}{b + cx} + C, \text{ when } b^{2} = ac$$
25.
$$\int \frac{(m + nx)dx}{a + 2bx + cx^{2}} = \frac{n}{2c} \log_{e} (a + 2bx + cx^{2}) + \frac{mc - nb}{c} \int \frac{dx}{a + 2bx + cx^{2}}$$
26. In
$$\int \frac{f(x)dx}{a + 2bx + cx^{2}}, \text{ if } f(x) \text{ is a polynominal of higher than the first degree, divide by the denominator before integrating.}$$
27.
$$\int \frac{dx}{(a + 2bx + cx^{2})^{p}} = \frac{1}{2(ac - b^{3})(p - 1)} \times \frac{b + cx}{(a + 2bx + cx^{3})^{p-1}} + \frac{(2p - 3)c}{(a + 2bx + cx^{3})^{p-1}} \int \frac{dx}{(a + 2bx + cx^{3})^{p-1}} + \frac{mc - nb}{c} \int \frac{dx}{(a + 2bx + cx^{3})^{p-1}} + \frac{mc - nb}{c} \int \frac{dx}{(a + 2bx + cx^{3})^{p-1}} + \frac{mc - nb}{c} \int \frac{dx}{(a + 2bx + cx^{3})^{p-1}} dx$$
29.
$$\int x^{m-1}(a + bx)^{n} dx = \frac{x^{m-1}(a + bx)^{n+1}}{(m + n)b} - \frac{(m - 1)a}{(m + n)b} \int x^{m-2}(a + bx)^{n} dx$$

 $= \frac{x^{m}(a + bx)^{n}}{m + n} + \frac{na}{m + n} \int x^{m-1}(a + bx)^{n-1} dx$

$$\int \sin x \cos x dx = \frac{1}{2} \sin^{2} x + C$$
64.
$$\int \frac{dx}{\sin x \cos x} = \log_{\theta} \tan x + C$$
65.
$$\int \cos^{n} x dx = -\frac{\cos x \sin^{n-1}x}{n} + \frac{n-1}{n} \int \sin^{n-2} x dx$$
66.
$$\int \cos^{n} x dx = \frac{\sin x \cos^{n-1}x}{n} + \frac{n-1}{n} \int \sin^{n-2} x dx$$

[•] If n is an odd number, substitute $\cos x = z$ or $\sin x = s$.

67.
$$\int \tan^{n} x \, dx = \frac{\tan^{n-1} x}{n-1} - \int \tan^{n-2} x \, dx$$
68.
$$\int \cot^{n} x \, dx = -\frac{\cot^{n-1} x}{n-1} - \int \cot^{n-2} x \, dx$$
69.
$$\int \frac{dx}{\sin^{n} x} = -\frac{\cos x}{(n-1)\sin^{n-1} x} + \frac{n-2}{n-1} \int \frac{dx}{\sin^{n-2} x}$$
70.
$$\int \frac{dx}{\cos^{n} x} = \frac{\sin x}{(n-1)\cos^{n-1} x} + \frac{n-2}{n-1} \int \frac{dx}{\cos^{n-2} x}$$
71.
$$\int \sin^{p} x \cos^{q} x \, dx = \frac{\sin^{p+1} x \cos^{q+1} x}{p+q} + \frac{q-1}{p+q} \int \sin^{p} x \cos^{q-2} x \, dx$$

$$= -\frac{\sin^{p+1} x \cos^{q+1} x}{p+q} + \frac{p-1}{p+q} \int \sin^{p} x \cos^{q} x \, dx$$
72.
$$\int \sin^{p} x \cos^{q} x \, dx = -\frac{\sin^{p+1} x \cos^{q+1} x}{p-1} + \frac{q-p-2}{p-1} \int \sin^{p+2} x \cos^{q} x \, dx$$
73.
$$\int \sin^{p} x \cos^{-q} x \, dx = \frac{\sin^{p+1} x \cos^{q+1} x}{q-1} + \frac{q-p-2}{q-1} \int \sin^{p} x \cos^{-q+2} x \, dx$$

$$= \frac{1}{\sqrt{b^{2}-a^{2}}} \log_{b} \frac{b+a \cos x+\sin x \sqrt{b^{2}-a^{2}}}{a+b \cos x} + C, \text{ when } a^{2} > \frac{1}{\sqrt{b^{2}-a^{2}}} \log_{b} \frac{b+a \cos x}{a+b \cos x} + C$$
75.
$$\int \frac{\cos x \, dx}{a+b \cos x} = \frac{x}{b} - \frac{a}{b} \int \frac{dx}{a+b \cos x} + C$$
76.
$$\int \frac{\sin x \, dx}{a+b \cos x} = -\frac{1}{b} \log_{e} (a+b \cos x) + C$$
77.
$$\int \frac{A+B \cos x+C \sin x}{a+b \cos x} \, dx = A \int \frac{dy}{a+p \cos y} + (B \cos u+C \sin u) \int \frac{\cos y \, dy}{a+p \cos y} - (B \sin u-C \cos u) \int \frac{\sin y \, d}{a+p \cos y} + (B \cos u+C \sin u) \int \frac{\cos y \, dy}{a+p \cos y} - (B \sin u-C \cos u) \int \frac{\sin y \, d}{a+p \cos y} + (B \cos u+C \sin u) \int \frac{\cos y \, dy}{a+p \cos y} - (B \sin u-C \cos u) \int \frac{\sin y \, d}{a+p \cos x} + C$$
79.
$$\int e^{ax} \cos bx \, dx = \frac{a \sin bx-b \cos bx}{a^{2}+b^{3}} e^{ax} + C$$
80.
$$\int \sin^{-1} x \, dx = x \sin^{-1} x + \sqrt{1-x^{2}} + C$$
81.
$$\int \cos^{-1} x \, dx = x \cos^{-1} x - \sqrt{1-x^{2}} + C$$
81.
$$\int \cos^{-1} x \, dx = x \cos^{-1} x - \sqrt{1-x^{2}} + C$$

82. $\int \tan^{-1} x \, dx = x \tan^{-1} x - \frac{1}{2} \log_{a} (1 + x^{2}) + C$ 83. $\int \cot^{-1} x \, dx = x \cot^{-1} x + \frac{1}{2} \log_{a} (1 + x^{2}) + C$

[•] If p or q is an odd number, substitute $\cos x = s$ or $\sin x = s$.

84.
$$\int \sinh x \, dx = \cosh x + C$$
85.
$$\int \tanh x \, dx = \log_{\circ} \cosh x + C$$
86.
$$\int \cosh x \, dx = \sinh x + C$$
87.
$$\int \coth x \, dx = \log_{\circ} \sinh x + C$$
88.
$$\int \operatorname{sech} x \, dx = 2 \tan^{-1} (e^{x}) + C$$
89.
$$\int \operatorname{csch} x \, dx = \log_{\circ} \tanh (x/2) + C$$
90.
$$\int \sinh^{2} x \, dx = \frac{1}{2} \sinh x \cosh x - \frac{1}{2}x + C$$
91.
$$\int \cosh^{2} x \, dx = \frac{1}{2} \sinh x \cosh x + \frac{1}{2}x + C$$
92.
$$\int \operatorname{sech}^{2} x \, dx = \tanh x + C$$
93.
$$\int \operatorname{csch}^{2} x \, dx = -\coth x + C$$

DEFINITE INTEGRALS

The definite integral of f(x)dx from x = a to x = b, denoted by $\int_a^b f(x)dx$, is the limit (as n increases indefinitely) of a sum of n terms:

$$\int_a^b f(x)dx = \lim_{n = \infty} [f(x_1)\Delta x + f(x_2)\Delta x + f(x_2)\Delta x + \dots + f(x_n)\Delta x],$$

built up as follows: Divide the interval from a to b into n equal parts, and call each part $\Delta x_1 = (b - a)/n$; in each of these intervals take a value of x (say x_1, x_2, \ldots, x_n), find the value of the function f(x) at each of these points, and multiply it by Δx , the width of the interval; then take the limit of the sum of the terms thus formed, when the number of terms increases indefinitely, while each individual term approaches zero.

Geometrically, $\int_a^b f(x)dx$ is the area bounded by the curve y = f(x), the x-axis, and the ordinates x = a and x = b (Fig. 8); that is, briefly, the "area under the curve, from a to b." The fundamental theorem for the evaluation of a definite integral is the following:

integral is the following:
$$\int_a^b f(x)dx = \left[\int f(x)dx\right]_{z=b} - \left[\int f(x)dx\right]_{z=a};$$
that is, the definite integral is equal to the difference be-

tween two values of any one of the indefinite integrals of the function in question. In other words, the limit of a sum can be found whenever the function can be integrated.

Properties of Definite Integrals.

$$\int_a^b = -\int_b^a; \ \int_a^c + \int_a^b = \int_a^b.$$

THE MEAN-VALUE THEOREM FOR INTEGRALS.

$$\int_a^b F(x) f(x) dx = F(X) \int_a^b f(x) dx,$$

provided f(x) does not change sign from x = a to x = b; here X is some (unknown) value of x intermediate between a and b.

THEOREM ON CHANGE OF VARIABLE. In evaluating $\int_{x=a}^{x=b} f(x) dx$, f(x) dx may be replaced by its value in terms of a new variable t and dt, and x=a and x=b by the corresponding values of t, provided that throughout the interval the relation between x and t is a one-to-one correspondence (that is, to each value of x there corresponds one and only one value of t, and to each value of t there corresponds one and only one value of x).

DIFFERENTIATION WITH RESPECT TO THE UPPER LIMIT. If, b is variable, then $\int_a^b f(x)dx$ is a function of b, whose derivative is

$$\frac{d}{db}\int_a^b f(x)dx = f(b).$$

DIFFERENTIATION WITH RESPECT TO A PARAMETER.

$$\frac{\partial}{\partial c} \int_a^b f(x,c)dx = \int_a^b \frac{\partial f(x,c)}{\partial c}dx.$$

Functions Defined by Definite Integrals. The following definite integrals have received special names, and their values have been tabulated; see, for example, B. O. Peirce's "Table of Integrals."

- 1. Elliptic integral of the first kind = $F(u, k) = \int_0^{u} \frac{dx}{\sqrt{1 k^2 \sin^2 x}} (k^2 < 1)$
- 2. Elliptic integral of the second kind = $E(u, k) = \int_{a}^{u} \sqrt{1 k^2 \sin^2 x} dx$ $(k^2 < 1)$
- 3, 4. Complete elliptic integrals of the first and second kinds; put $u = \pi/2$ in (1) and (2).
 - 5. The Probability integral = $\frac{2}{\sqrt{\pi}} \int_0^x e^{-x^2} dx$
 - 6. The Gamma function = $\Gamma(n) = \int_{a}^{\infty} x^{n-1}e^{-x}dx$

Approximate Methods of Integration. Mechanical Quadrature.

- (1) Use Simpson's rule. See p. 106.
- (2) Expand the function in a power series, and integrate term by term.
- (3) Plot the area under the curve y = f(x) from x = a to x = b on squared paper and measure this area roughly by "counting squares," or more accurately, by the use of a planimeter (\$14 to \$35; instruction for use with each instrument).
- (4) Coradi's Mechanical Integraph (\$240) provides a means of drawing on paper the curve $y = \int f(x)dx$, when the curve y = f(x) is given, and can be used to facilitate the solution of certain differential equations. Full instructions for use with each instrument.

Double Integrals. The notation $\int \int f(x, y) dy dx$ means $\int \left\{ \int f(x, y) dy \right\} dx$, the limits of integration in the inner, or first, integral being functions of x (or constants).

Example. To find the weight of a plane area whose density, w, is variable, say w = f(x, y). The weight of a typical element, dx dy, is f(x, y)dx dy. Keeping x and dx constant, and summing these elements from, say, y = $F_1(x)$ to $y = F_2(x)$, as determined by the shape of the

Fig. 9.

boundary, the weight of a typical strip perpendicular to the x-axis is

 $dx \int_{y=F_1(x)}^{y=F_2(x)} y = F_1(x)$ $dx \int_{y=F_1(x)}^{y=F_2(x)} y = F_1(x)$ weight of a typical strip perpendicular to the x-axis is $\int_{y=F_1(x)}^{y=F_2(x)} y = F_1(x)$

weight of the whole area is $\int_{x=a}^{x=b} \begin{cases} y = F_2(x) \\ f(x, y) dy \end{cases}$, or, briefly, $\int \int f(x, y) dy dx$.

DIFFERENTIAL EQUATIONS

An ordinary differential equation is one which contains a single independent variable, or argument, and a single dependent variable, or function, with its derivatives of various orders. A partial differential equation is one which contains a function of several independent variables, and its partial derivatives of various orders. The order of a differential equation is the order of the highest derivative which occurs in it. A solution of a differential equation is any relation between the variables, which, when substituted in the given equation, will satisfy it. The general solution of an ordinary differential equation of the nth order will contain n arbitrary constants. A differential equation is usually said to be solved when the problem is reduced to a simple quadrature, that is, an integration of the form $y = \int f(x) dx$.

Methods of Solving Ordinary Differential Equations

DIFFERENTIAL EQUATIONS OF THE FIRST ORDER

- (1) If possible, separate the variables; that is, collect all the x's and dx on one side, and all the y's and dy on the other side; then integrate both sides, and add the constant of integration.
- (2) If the equation is homogeneous in x and y, the value of dy/dx in terms of x and y will be of the form $\frac{dy}{dx} = f\left(\frac{y}{x}\right)$. Substituting y = xt will enable

the variables to be separated. Solution: $\log_{\epsilon} x = \int \frac{dt}{f(t) - t} + C$.

(3) The expression f(x,y)dx + F(x,y)dy is an exact differential if $\frac{\partial f(x,y)}{\partial y} = \frac{\partial F(x,y)}{\partial x} (= P, \text{ say})$. In this case the solution of f(x,y)dx + F(x,y)dy = 0 is

or
$$\int f(x,y)dy + \int [F(x,y) - \int Pdx]dy = C$$
$$\int F(x,y)dy + \int [f(x,y) - \int Pdy]dx = C$$

(4) Linear differential equation of the first order: $\frac{dy}{dx} + f(x) \cdot y = F(x)$.

Solution: $y = e^{-P} \left\{ \int e^{P} F(x) dx + C \right\}$, where $P = \int f(x) dx$.

- (5) Bernoulli's equation: $\frac{dy}{dx} + f(x) \cdot y = F(x) \cdot y^n$. Substituting $y^{1-n} = v$ gives $\frac{dv}{dx} + (1-n)f(x) \cdot v = (1-n)F(x)$, which is linear in v and x.
- (6) Clairaut's equation: y = xp + f(p), where p = dy/dx. The solution consists of the family of lines given by y = Cx + f(C), where C is any constant, together with the curve obtained by eliminating p between the equations y = xp + f(p) and x + f'(p) = 0, where f'(p) is the derivative of f(p).

DIFFERENTIAL EQUATIONS OF THE SECOND ORDER

(7)
$$\frac{d^2y}{dx^2} = -n^2y. \quad \text{Solution: } y = C_1 \sin(nx + C_2)$$
or $y = C_3 \sin nx + C_4 \cos nx$

(8)
$$\frac{d^2y}{dx^2} = +n^2y$$
. Solution: $y = C_1 \sinh{(nx + C_2)}$
or $y = C_2 e^{nx} + C_4 e^{-nx}$

(9)
$$\frac{d^3y}{dx^3} = f(y)$$
. Solution: $x = \int \frac{dy}{\sqrt{C_1 + 2P}} + C_2$, where $P = ff(y) dy$.

(10)
$$\frac{d^2y}{dx^2} = f(x). \text{ Solution: } y = \int Pdx + C_1x + C_2, \text{ where } P = \int f(x)dx$$
 or $y = xP - \int xf(x)dx + C_1x + C_2$

(11)
$$\frac{d^2y}{dx^2} = f\left(\frac{dy}{dx}\right)$$
. Putting $\frac{dy}{dx} = z$, $\frac{d^2y}{dx^2} = \frac{dz}{dx}$, $x = \int \frac{dz}{f(z)} + C_1$ and $y = \int \frac{sdz}{f(z)} + C_2$; then eliminate z from these two equations.

(12) The equation for damped vibration:
$$\frac{d^3y}{dx^2} + 2b\frac{dy}{dx} + e^2y = 0.$$

Case I. If
$$a^2 - b^2 > 0$$
, let $m = \sqrt{a^2 - b^2}$. Solution:

$$y = C_1 e^{-bx} \sin(mx + C_2)$$
 or $y = e^{-bx} [C_3 \sin(mx) + C_4 \cos(mx)]$
Case II. If $a^2 - b^2 = 0$, solution is $y = e^{-bx} [C_1 + C_2x]$.

Case III. If $a^2 - b^2 < 0$, let $n = \sqrt{b^2 - a^2}$. Solution:

$$y = C_1 e^{-bx} \sinh (nx + C_2)$$
 or $y = C_2 e^{-(b+n)x} + C_4 e^{-(b-n)x}$

(13) $\frac{d^2y}{dx^2} + 2b\frac{dy}{dx} + a^2y = c$. Solution: $y = \frac{c}{a^2} + y_1$, where $y_1 =$ the solution of the corresponding equation with second member zero [see (12) above].

(14)
$$\frac{d^2y}{dx^3} + 2b\frac{dy}{dx} + a^2y = c\sin(kx)$$
. Solution:

$$y = R \sin(kx - S) + y_1$$
, where $R = c_1 \sqrt{(a^2 - k^2)^2 + 4b^2k^2}$,

 $\tan S = \frac{2bk}{a^2 - k^2}$, and $y_1 =$ the solution of the corresponding equation with second member zero [see (12) above].

(15)
$$\frac{d^3y}{dx^2} + 2b\frac{dy}{dx} + a^2y = f(x)$$
. Solution: $y = y_0 + y_1$, where $y_0 =$ any particular solution of the given equation, and $y_1 =$ the general solution of the

corresponding equation with second member zero [see (12) above].

If
$$b^2 > a^2$$
, $y_0 = \frac{1}{2\sqrt{b^2 - a^2}} \left\{ e^{m_1 x} \int e^{-m_1 x} f(x) dx - e^{m_2 x} \int e^{-m_2 x} f(x) dx \right\}$, where $m_1 = -b + \sqrt{b^2 - a^2}$ and $m_2 = -b - \sqrt{b^2 - a^2}$. If $b^2 < a^2$, let $m = \sqrt{a^2 - b^2}$; then $y_0 = \frac{1}{m} e^{-bx} \left\{ \sin(mx) \int e^{bx} \cos(mx) \cdot f(x) dx - \cos(mx) \int e^{bx} \sin(mx) \cdot f(x) dx \right\}$. If $b^2 = a^2$, $y_0 = e^{-bx} \left\{ x \int e^{bx} f(x) dx - \int x e^{bx} f(x) dx \right\}$.

GRAPHICAL REPRESENTATION OF FUNCTIONS

For graphical methods in statistics, etc., see W. C. Brinton's "Graphical Methods for Presenting Facts"

EQUATIONS INVOLVING TWO VARIABLES

The Curve y = f(x). To represent graphically any function, y, of a single variable, x, lay off the values of x as abscissae along a uni-

formly graduated horizontal axis, whose positive direction (as usually chosen) runs to the right, and at each point on this x-axis erect a perpendicular (called an ordinate) whose length represents the value of y at that point. The unit of measurement for the y-scale, whose positive direction (as usually chosen) runs upward, need not be the same as the unit for the x-scale. Draw a

Fig. 1.

1

smooth curve through the extremities of the ordinates; this is the graph of the given function in rectangular co-ordinates, or the curve of the function.

To measure graphically the rate of change of the function at any point P(Fig. 1), draw the tangent at P; then rate of change at P = RT/PR, where RT and PR are measured in units of the y-axis and x-axis, respectively. This ratio, which is positive if RT runs upward, negative if RT runs downward, is equal to the derivative of the function at the point P (see p. 157),

Graphs of Important Functions. Figs. 2-9 show the graphs (in rectangular co-ordinates) of the most important elementary functions, namely: The linear function, y = mx + b (Fig. 2).

The power functions, $y = x^n$ [n positive (parabolic type); n negative (hyperbolic type)] (Fig. 3).

The exponential function, $y = 10^x$ or $y = e^x$, and the logarithmic function, $y = \log_{10} x$ or $y = \log_{0} x$ (Fig. 4).

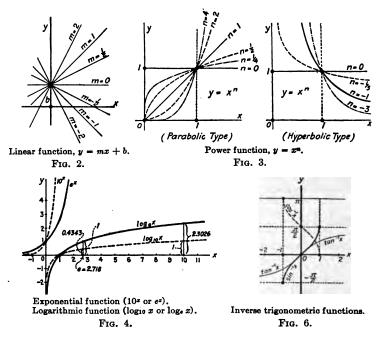

The trigonometric functions (Fig. 5), and the inverse trigonometric functions (Fig. 6).

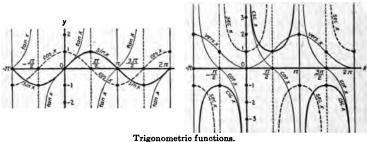

The hyperbolic functions (Figs. 7 and 8) and the inverse hyperbolic functions (Fig. 9).

Various special functions (Figs. 10-12).

By a slight modification, each of these diagrams may be made to represent a somewhat more general function than that for which it is primarily intended. For, if x is replaced by x - a in the equation, this merely requires re-numbering the x-axis so that each number is moved a units to the left; and similarly, if y is replaced by y - b in the equation, this merely requires re-numbering the y-axis so that each number is moved b units downward. (Such a change is called a translation of the curve to the right, or upward.) Further, if x is replaced by x/c [or y by y/c] in the equation, it is merely necessary to multiply each of the numbers written along the x-axis [or y-axis] by c, in order to adapt the graph to the new equation. (Such a change is called a "stretching" of the curve along one of the axes.)

Empirical Curves. Any set of values of two variables x and y can be represented by plotting the points (x,y) on rectangular co-ordinate paper, and drawing a smooth curve through these points. The points which correspond to actual data should be clearly indicated by small circles or crosses, intermediate points being spoken of as interpolated points. While this process of graphically interpolating a continuous series of points between given values is usually fairly safe, the process of extrapolation—that is, extending the curve beyond the range of the given values, is dangerous.

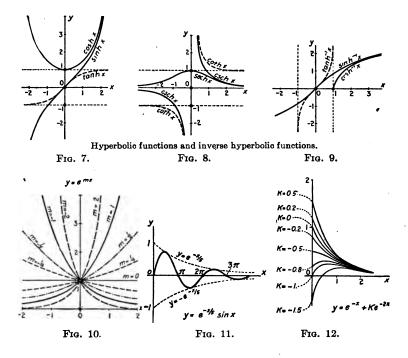

To Find a Mathematical Equation to Fit a Given Empirical Curve. This problem is one which in general requires much patience and ingenuity. Only the simplest cases can be mentioned here.

Fig. 5.

Case 1. If the given empirical curve is a straight line, then the law connecting the given values of x and y is y = mx + b, where m = the slope of the line, and b = the value of y at the point where the line crosses the y-axis. If

the points lie only approximately on a straight line, the best position for this line can usually be found by stretching a black thread among the points; or, assume a law of the form y = mx + b, and, by substituting in this formula n pairs of values of x and y, obtain n equations connecting the coefficients m and b; various pairs of these equations may then be solved for m and b, and the average of the results taken. Or, if great accuracy is required, all n of the equations may be solved for m and b by the method of least squares (p. 121).

If any law of the form f(x,y) = mF(x,y) + b is suspected, where f(x,y) and F(x,y) are any expressions involving either x or y or both x and y, such a law f(x,y) are any expressions involving either x or y or both x and y, such a law as be tested by plotting F(x,y) instead of x, and f(x,y) instead of y, on rectangular cross-section paper, and seeing whether or not the points lie on a straight line. If they do, the form of the law is verified, and the values of m and b can be read from the figure as before. For example, if $y^2 = mxy + b$, a straight line will be obtained by plotting y^2 against xy. Again, if xy = bx + my, a straight line will be obtained by plotting y against y/x, since the equation may be written y = b + m(y/x).

Case 2. If a law of the form $y = cx^n$ is suspected, plot the points (x,y) on logarithmic paper (see below).

Case 3. If a law of the form $y = c \cdot 10^{mx}$ [or $y = c \cdot e^{mx}$] is suspected, plot the points (x,y) on semi-logarithmic paper (see below).

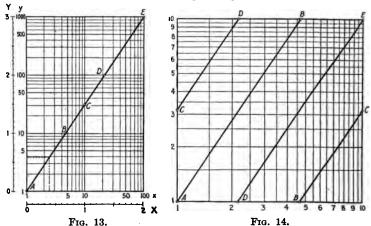

CASE 4. If the given curve resembles the logarithmic curve, $y = \log x$, interchange x and y and proceed as in Case 3.

CASE 5. If the given curve is a wavy line, resembling a sine or cosine curve, try an equation of the form $y = a \sin bx$ or $y = a \cos bx$. If the heights of the waves diminish as x increases, try an equation of the form $y = ae^{-nx} \sin bx$. [Note. Any periodic function (satisfying certain simple conditions) can be expressed by a Fourier's series (p. 162)].

Case 6. A great variety of functions can be represented approximately by a polynomial of the form $y = a + bx + cx^2 + dx^3 + ex^4 + \dots$, the first three or four terms being usually sufficient. To determine the coefficients a, b, c, \dots , most accurately, substitute in the formula all the given pairs of values of x and y, and solve the resulting equations for a, b, c, \dots by the method of least squares (p. 121).

CASE 7. Many simple curves can be represented approximately by an equation of the hyperbolic form, xy = c + bx + ay, where a, b, and c are determined by substituting the co-ordinates of three conspicuous points of the curve. The lines x = a and y = b are the asymptotes of the hyperbola. The equation may also be written (x - a)(y - b) = k, where k = ab + c.

Logarithmic Cross-section Paper. In this form of cross-section paper (Fig. 13), the distance from the origin to any point on the x- or y-axis is equal to the logarithm of the number written against that point. Thus, in Fig. 13 the distances (shown for clearness on two auxiliary scales X and Y) are the logarithms of the numbers written along x and y.

Accurately made logarithmic paper can be obtained from the principal dealers in draftmen's supplies. Logarithmic paper can be easily constructed, in case of need, by copying the logarithmic scale from any ordinary slide rule. The actual figures along the x- and y-axes are usually left for the user to insert; in so doing, notice that the numbers . . ., 0.01, 0.1, 1, 10, 100, . . ., or such of them as may be needed to cover any given range of values, must be placed at the points of division which separate the main squares. It is often convenient, however, to omit the decimal point, num-

bering each square independently from 1 to 10. The length of the side of one square is called the *unit* or base of the logarithmic paper; the larger the unit, the finer the possible subdivisions of the scale.

To plot a point (x,y) on logarithmic paper, for example, the point (3,5), means to find the point of intersection of the vertical line marked x=3 and the horizontal line marked y=5. In interpolating between two lines, account should be taken of the fact that the divisions are not of uniform length.

Any equation of the form $y = cx^n$ when plotted on logarithmic paper will be represented by a straight line whose slope is n. For, if $y_1 = cx_1^n$ and $y_2 = cx_2^n$, then $y_1/y_2 = (x_1/x_2)^n$, or $(\log y_1 - \log y_2)/(\log x_1 - \log x_2) = n$. The slope must be measured by aid of an auxiliary uniform scale.

EXAMPLE. Let $y = x^{3/2}$. When x = 1, y = 1; plot this point A on the logarithmic paper, and draw the straight line AE with a slope equal to $\frac{1}{2}$ (Fig. 13). By the aid of this line, the value of y for any value of x between 1 and 100 can be read off directly; for example, if x = 2.50, y = 3.95, as shown by dotted lines, so that $(2.50)^{3/2} = 3.95$. To find the value of y for any value of x outside this range, note that moving the decimal point 2 places in x is equivalent to moving it 3 places in y. The line shown in Fig. 13 is thus equivalent to a complete table of three-halves powers.

It will be noticed that this line crosses four squares of the logarithmic paper. By superposing these four squares the whole diagram may be condensed into a single square (Fig. 14), in which, however, the scales for x and y now give only the sequence of digits in the answer, the position of the decimal point having to be determined by inspection.

To determine whether a given set of values, x and y, satisfies a law of the form $y = cx^n$, plot the values on logarithmic paper, and see whether they lie on a straight line; if they do, then the given values satisfy a law of this form; moreover, the slope of the line gives the value of n, and the value of y when x = 1 gives the value of \dot{c} .

If the plotted points fail to lie exactly in line, but form a curve slightly concave upward, try subtracting some constant b from all the y's, that is, move each point downward a distance equal to b units of the y-scale at that point. If it proves possible to choose b so that the resulting points lie in line, then the original values obey a law of the form $y-b=cx^n$, where n is again the slope of the line, and c is the value of y-b when x=1. (Conversely, if the curve is concave downward, try adding b to all the y's; that is, move each point upward; if the new points lie in line, the original values obey a law of the form $y+b=cx^n$.) Another method of "straightening" the curve consists of adding some constant, $\pm a$, to all the values of x, which has the effect of shifting all the points to the right or left (by varying amounts); if this method succeeds, the original values obey a law of the form $y=c(x+a)^n$.

Semi-logarithmic Cross-section Paper*. This form of paper (Fig. 15) has a logarithmic scale along y and a uniform scale along x. The "scale value," k, of the paper is the number which stands, on the x-axis, at a distance from the origin equal to the width of one of the main horizontal strips. Thus, in Fig. 15, each number shown along the auxiliary scale Y is the logarithm of the corresponding number along y, and each number shown along the auxiliary scale X is 1/kth of the corresponding number along x (here k = 5). The number k, which may be chosen at pleasure, should be taken equal to some simple integer, as 1, 2, or 5, or some integral power of 10.

In preparing the paper for use it is important to notice that the numbers ..., $0.01, 0.1, 1, 10, 100, \ldots$ (or such of them as may be needed in any given case) must be placed along the y-axis at the points which mark the main lines of division between the horizontal strips; while the numbers ..., $-2k, -k, 0, +k, +2k, \ldots$ (or such of them as may be needed) must be placed along the x-axis at uniform intervals, each interval (from 0 to k, from k to 2k, etc.) being equal to the width of one of the main horizontal strips. The width of one of these strips is called the unit or base of the semi-

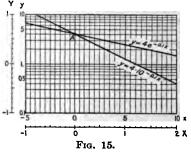

[•] Made by the Educational Exhibition Co.. 26 Custom House St., Providence, B. L.

logarithmic paper; the larger the unit, the finer the possible subdivisions of the scale.

To plot a point (x,y), as x=3, y=5, on semi-logarithmic paper means to find the point of intersection of the vertical line marked x=3 with the horizontal line marked y=5.

Any equation of the form $y = c \cdot 10^{mz}$ [or $y = c \cdot e^{mx}$] when plotted on semi-logarithmic paper with scale value k, will be represented by a straight line whose slope is km [or $0.4343 \ km$.]. By a suitable choice of the scale value k, any given range of values of x can be brought within the size of the paper. Note that $e = 10^{0.4343}$

EXAMPLE. Given $y = 4 \cdot 10^{-6 \cdot 1x}$ [or $y = 4 \cdot x^{-0 \cdot 1x}$]. In Fig. 15, when x = 0, y = 4. By plotting this point (A) on the semi-logarithmic paper, with scale value 5, and drawing through it a straight line with

slope equal to -0.5 [or -0.217] a graphical representation is obtained from which, for any value of x, the corresponding value of y can be read off. If it is desired to condense the figure, several horizontal strips may be superposed on a single strip; this of course renders the decimal point in the y-scale undetermined (unless a separate y-scale is provided for each section of the graph).

In order to determine whether a given set of values of x and y satisfy a law of the form $y = c \cdot 10^{mz}$ [or $y = c \cdot e^{mz}$], plot the values of x and y on semi-logarithmic paper, with a suitable scale value k, and see whether they lie on a straight line; if they do so, the law is satisfied, and the values of m and c may be found as follows: m = the slope of the line divided by k [or the slope of the line divided by 0.4343k], and c = the value of y when x = 0.

If the plotted points fail to lie exactly in line, but form a curve slightly concave upward, try subtracting some constant b from all the y's, and plot the values thus modified;

if b can be so chosen that the revised points lie in line, then the original values obey a law of the form $y-b=c\cdot 10^{mx}$ [or $y-b=c\cdot e^{mz}$], where m and c are to be found as before. If the curve is concave downward, add b, instead of subtracting; and replace y-b by y+b in the law.

Curves in Polar Co-ordinates. Any function, τ , of a single variable, θ , can be represented by a curve in polar co-ordinates (p. 137). Lay off the given values of θ as angles, the initial line Ox running toward the right, and the counterclockwise direction about the origin being taken as positive. Along the terminal side of each angle θ ,

lay off the corresponding value of r, forward if r is positive, backward if r is negative; and pass a smooth curve through the points thus determined.

The rate of change of r with respect to θ at a given point P is represented graphically as follows (Fig. 16): On the tangent at P drop a perpendicular OM from the origin; then r(MP/OM) represents the rate of change, $dr/d\theta$, provided θ is measured in radians. Specially ruled polar co-ordinate paper is supplied by dealers in drafting supplies.

EQUATIONS INVOLVING THREE VARIABLES

The Surface z = f(x, y). Any function, z, of two variables, x and y, may be represented by a surface, as follows: Plot the given pairs of values of x and y as points in a horizontal x, y plane, called the base plane; at each of these points erect an ordinate, parallel to a vertical axis z, and representing

by its length the value of z at that point. Then conceive a smooth surface passed through the extremities of these ordinates: this surface is said to represent the function. In practice, the ordinates may be made by implanting stiff vertical rods in a horizontal board of soft wood which serves as the base plane; the surface may then be constructed by filling in the spaces with plaster of Paris. Or, more simply, pieces of cardboard may be cut out to represent parallel plane sections of the surface, and then stood on edge in slots cut in the board to receive them. The units employed along x, y, and z need not be equal to each other.

Contour-line Charts. All the points of a surface z = f(x, y) which are at any given height above the base plane form a curve on the surface, called a contour line of the surface. If each of these contour lines be projected on the base plane, and each labeled with the value of z to which it corresponds, a complete representation of the function z = f(x, y) is obtained, all in one plane. A topographical map, with contour lines showing elevations above the sea, and a weather map, with contour lines showing barometric pressure, are familiar examples. If there are several values of z corresponding to any given point (x, y), there will be several contour lines whose projections pass through that point.

Contour-line Charts for Simultaneous Equations [of the form z = f(x,y), w = F(x,y)]. In Fig. 17, plot the function z = f(x,y) by contour

lines on an x,y plane, and plot the function w = F(x,y) by contour lines on the same x,y plane. Then every point on the diagram (either directly or by interpolation) is the intersection of four curves—an x-curve, a y-curve, a z-curve, and a w-curve. Here, by "curve" is meant any line, straight or curved. By the aid of such a diagram, when the values of any two of these four variables are given, the values of the other two can be found. The method of use consists simply in entering the diagram along the two given curves (or lines), tracing them to their point of intersection, and then coming out again along the

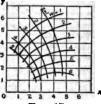

Fig. 17.

two curves (or lines) whose values are required. The best manner of numbering the curves is indicated in the figure.

Alignment Charts for Three Variables, t, u, v. Any relation between three variables, t, u, v, which can be thrown into one of the forms listed in later paragraphs, can be represented graphically by a very convenient form of diagram called an alignment chart. In the simplest form of an alignment chart for three variables there are three scales (straight or curved), along which the values of the three variables, t, u, v, are marked in such a way that any three values of t, u, v which satisfy the given equation are represented by three points which lie in line. Hence, if the values of any two of the variables are given, the corresponding value of the third can be found by simply drawing a straight line through the two given points and reading the value of the point where it crosses the third scale.

The most important methods of constructing alignment charts for three variables are described below. Where several methods are applicable in a given case, the best one must be determined largely by trial. For further information see M. d'Ocagne, "Traité de Nomographie" (Gauthier-Villars, Paris); Carl Runge, "Graphical Methods" (Columbia University Press); J. B. Peddle, "Construction of Graphical Charts" (McGraw-Hill); see also page 185.

Notation. In each of the equations which follow, U stands for any function of u alone, V for any function of v alone, and $F_1(t)$, $F_2(t)$ for any functions of t alone. Any of these functions may reduce to a constant. The axes of x, y, and y' which are mentioned are of merely temporary use in constructing the diagram, and the letters x, y, y' should not be written on the chart. It is not necessary that the axes be at right angles, provided the x of a point is always measured parallel to the x-axis, and its y parallel to the y-axis.

Method 1. Given, an equation which can be thrown into the form $U \cdot F_1(t) + V \cdot F_2(t) = 1$.

where, for the given range of values of u and v, the largest variations in U and V are less than a certain number m.

Draw a pair of (temporary) x,y axes (Fig. 18), and through the point x = 1 draw a third axis, which may be called the axis of y', parallel to the axis of y. In ordinary cases, the unit of measurement along x should be nearly equal to the full width of the paper. Now choose a unit for y and y' such that m times this unit will about equal the height of the paper, and plot, in the usual way, the points (x,y) given by

F1g. 18.

$$x = \frac{F_2(t)}{F_1(t) + F_2(t)}, \quad y = \frac{1}{F_1(t) + F_2(t)}$$

labeling each point with the value of t to which it corresponds. Connect these points by a smooth curve, which gives the t-scale of the diagram. [If $F_1(t)/F_2(t) = a$ constant, the t-scale will prove to be a straight line parallel to the y-axis.]

Then, using the same units as above, plot along y the points given by y = U, labeling each point with the corresponding value of u; and plot along y' the points given by y' = V, labeling each of these points with the corresponding value of r. This gives the u- and r-scales of the diagram. The three scales being thus constructed, the x-axis may now be erased, and the diagram is ready for use. Any three points t, u, v which lie in line correspond to three values of t, u, r, which satisfy the given equation. The numbering on each scale should be shown at sufficiently frequent intervals to permit of easy interpolation.

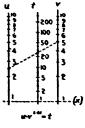

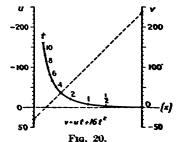

Fig. 19.

EXAMPLE 1 (Fig. 19). Let $uv^{1-\alpha} = t$. By taking the logarithm of both sides, and dividing through by $\log t$, reduce the equation to the form $(\log u) (1/\log t) + (\log v) \times (1.41 \log t) = 1$. Here $V = \log u$, $V = \log v$, $F_1(t) = 1/\log t$, $F_2(t) = 1.41/\log t$, and u = 1.41/2.41 = 0.585, $u = (1.2.41)\log t$.

EXAMPLE 2 (Fig. 20). Let $v = ut + 16t^2$, which reduces to the form $(-u/16)(1/t) + (v/16)(1/t^2) = 1$. Here U = -u/16, V = v/16, $F_1(t) = 1/t$, $F_2(t) = 1/t^2$ and x = 1/(1+t), $y = t^2/(1+t)$.

NOTE. If $m=\infty$, values of u and v which give large values of U and V cannot be shown within the limits of the paper. In such cases, the chart may be supplemented by a second chart, made according to Method 2, below.

Method 2. Given, an equation which can be thrown into the form

$$\frac{F_{1}(t)}{U} + \frac{F_{2}(t)}{V} = 1,$$

where, for the given range of values of u and v, the largest variation in U is less than a certain number m, and the largest variation in V is less than a certain number n.

Draw a pair of temporary x,y axes, and having chosen a unit for the x-axis equal to about (1/m)th of the width of the paper, and a unit for the y-axis equal to about (1/n)th of the height, plot the points (x,y) given by

$$x = F_1(t), y = F_2(t),$$

labeling each point of this curve with the value of t to which it corresponds. Connect these points by a smooth curve, which gives the t-scale of the diagram. [If $F_1(t)/F_2(t) = a$ constant, the t-scale will be a straight line through the origin.]

Then, using the same units as above, plot along x the values of U, labeling each point with the corresponding value of u; and plot along y the values of V, labeling each point with the corresponding value of v. This gives the u- and v-scales of the diagram. On the chart as thus completed, any three points t, u, v which lie in line correspond to three values of t, u, v which satisfy the given equation.

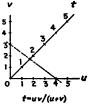

Fig. 21.

EXAMPLE (Fig. 21). Let t = (uv)/(u+v), which may be written in the form t/u + t/v = 1. Here U = u, V = v, $F_1(t) = t$, $F_2(t) = t$.

NOTE. If $m=\infty$ and $n=\infty$, values of u and v which give large values of U and V cannot be shown within the limits of the paper. In such cases the chart may be supplemented by a second chart, made according to Method 1, above.

Method 3. Given, an equation which can conveniently be thrown into the form

$$F_2(t) = V \cdot F_1(t) + U,$$

where, for the given range of values of t, the largest variation in $F_1(t)$ is less than a certain number m, and the largest variation in $F_2(t)$ is less than a certain number n.

Draw a pair of temporary x,y axes, and, having chosen a unit for x equal to about (1/m)th of the width of the paper and a unit for y equal to about (1/n)th of the height, plot the points (x,y) given by

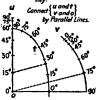

$$x = F_1(t), y = F_2(t),$$

labeling each point of the curve with the value of t to which it corresponds. Connect these points by a smooth curve, which forms the t-scale. Next, using the same unit for y as above, plot along the y-axis the values of U, labeling each point with the corresponding value of u. This gives the u-scale Finally, with the origin as center, and any convenient radius, draw a circle cutting the x-axis in A. Along this circular arc, starting from A in the counterclockwise direction, lay off the angles whose slopes are equal to V, labeling each point of the arc with the value of v to which it corresponds.

form

This gives the v-scale, which in this case, however, plays a peculiar rôle, since, in using this form of chart, two straight lines are required instead of one. Thus:

In order to determine whether three values, t, u, v, satisfy the given equation, lay one straight line through the points t and u, and another straight line through the point v and the origin; if these lines are parallel, the three values of t, u, v satisfy the equation. will be noticed that the function of the v-scale here is to measure, in a certain sense, the slope of the line ioining t and u. A chart of this type may be called an alignment chart with a sliding scale for one of the variables."

sinu-sin 60°sin t-cos 60°cost cosv Fig. 22.

Example (Fig. 22). Let $\sin u = \sin 60^{\circ} \sin t - \cos 60^{\circ} \cos t$ cos v, which may be put in the form

 $(\sin 60^{\circ} \sin t) = \cos v (\cos 60^{\circ} \cos t) + \sin u.$

Here $F_1(t) = \cos 60^{\circ} \cos t$, $F_2(t) = \sin 60^{\circ} \sin t$, $U = \sin u$, $V = \cos v$. Method 4. Given, an equation which can be reduced to the

Fig. 23.

 $U \cdot F(t) + V = 0,$

where, for the given range of values of u and v, the largest variations in U and V are less than a certain number m.

In Fig. 23, draw temporary axes x, y, and y', and

choose the units as in Method 1. To construct the t-scale, which will now coincide with the x-axis, plot along x the points for which

Fig. 24.

$$x = \frac{1}{1 + F(t)},$$

labeling each point with the value of t to which it corresponds. The u-scale, along the axis of y, and vscale, along the axis of y', are constructed exactly as in Method 1, and the finished chart is used in the same way.

Example (Fig. 24). Let $v = 0.196 t^2 u$, where u is to range from 0 to 15,000 and v from 0 to 150,000. The equation may be written in the form (-10 u) $(0.0196t^3) + v$ = 0. Here U = -10 u, V = v, $F(t) = 0.0196t^3$.

Note. If $m = \infty$, values of u and v which give large values of U and V cannot be shown within the limits of the paper.

EQUATIONS INVOLVING FOUR VARIABLES

[For simultaneous equations of the form z = f(x,y), w = F(x,y), see p. 179.]

Alignment Charts for Four Variables. The extension of the methods of the alignment chart to the case of four variables, say r, s, u, v, consists essentially in replacing the t-scale of the earlier diagram by a network of two scales, one for r and one for s. The point where a curve $r = r_1$ and a curve $s = s_1$ intersect may be spoken of as the point (r_1, s_1) . In the following equations, U denotes as before any function of u alone, V any function of v alone: while $F_1(r,s)$ and $F_2(r,s)$ represent any functions of r and s.

Method 1a. Given, an equation of the form

$$U \cdot F_1(r,s) + V \cdot F_2(r,s) = 1.$$

Draw axes x, y, and y' as in Method 1, and plot the network of curves given by the equations

$$x = \frac{F_2(r,s)}{F_1(r,s) + F_2(r,s)}, \qquad y = \frac{1}{F_1(r,s) + F_2(r,s)}$$

[To do this (Fig. 25), find the point (x,y) that corresponds to each given pair of values of r and s, by direct substitution in the equations for x and y. Connect all the points for which r=1 by a curve, and label it r=1; connect all the points for which r = 2 by another curve, and label it r = 2; etc. gives the family of r-curves. Similarly, through all the points for which s=1 draw a curve labeled s=1; through all the points for which s=2draw a curve labeled s = 2; etc. This gives the family of s-curves, intersecting the family of r-curves. Note, however, that if it is possible to eliminate s (or r) from the equations that give x and y, the resulting equation in x, y, and r (or x, y, and s) can often be plotted directly for each given value of r(or of s).]

Next, construct the u- and v-scales along the axes of y and y' as in Method 1. [The letters x, y, and y', and the units used in plotting along these axes, should be omitted from the finished diagram, as should also the axis of x.

In the chart, as thus completed, any three points, (r,s), u, and v which lie in a straight line, correspond to values of r, s, u, v which satisfy the given equation. Hence, when any three of these four values are given, the fourth can be found from the chart.

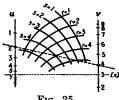

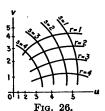

Fig. 25.

Method 2a. Given, an equation of the form

$$\frac{F_1(r,s)}{U} + \frac{F_2(r,s)}{V} = 1.$$

Draw axes of x and y as in Method 2, and plot the network of curves given by $x = F_1(r,s), y = F_2(r,s).$

To do this, follow the plan outlined for a similar case under Method 1a. labeling each curve of the r-family (Fig. 26) with the corresponding value of r. and each curve of the s-family with the corresponding value of s. Next, construct the u- and v-scales along the x- and y-axes, precisely as in Method 2. Then any three points, (r,s), u, and v, which lie in a straight line correspond to values of r, s, u, v which satisfy the given equation.

Method 3a. Given, an equation of the form

$$F_2(r,s) = V \cdot F_1(r,s) + U$$
.

Draw axes of x and y, as in Method 3, and plot the network of curves given by $x = F_1(r,s)$, $y = F_2(r,s)$, following the plan outlined for a similar case under Method 1a, and labeling each curve of the r-family (or s-family) with the value of r (or s) to which it corresponds. Next, construct the u-scale along the y-axis, and the v-scale along a circular arc, precisely as in Method 3. Then any three points, (r,s) u, and v, which are so related that the line through (r,s) and u is parallel to the line joining v with the origin, will correspond to values of r, s, u, v which satisfy the given equation.

Example for Method 3a (Fig. 27). Let oot $v = \cot r \cos s + \csc r \sin s \cot u$, which may be written (cos r cot s) = $\cot v$ (sin r cos s) — $\cot u$. Here $U = -\cot u$, $V = \cot v$, $F_1(r,s) = \sin r \cos s$, $F_2(r,s) = \cos r \cot s$, whence $\frac{x^2}{\cos^2 s} + \frac{y^2}{\cot^2 s} = 1$, $\frac{x^2}{\sin^2 r} - \frac{y^2}{\cos^2 r} = 1$, so that the s-curves are ellipses and the r-curves hyperbolas.

Parallel Charts, or Proportional Charts, for Four Variables. In the following methods of representation there are four scales, one for each of the

four variables, and the method of using the diagram consists in connecting two pairs of points by parallel lines.

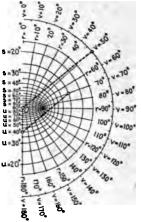

Method \triangle . Given, an equation of the form

$$R - S = U - V$$

where R, S, U, V are any functions of the variables r, s, u, v, respectively. [It will be noted that any proportion R/S = U/V can at once be thrown into this form by taking the logarithm of both sides.]

In Fig. 28, draw four vertical axes, y_1 , y_2 , y'_1 ,

 y'_2 , such that the distance between y_1 and y'_1 (which may be zero) is equal to the distance between y_2 and y'_2 , and so that the four zero points lie in line. Along these axes, using the same unit for all, plot the points given by $y_1 = R$, $y'_1 = S$, $y_2 = U$, $y'_2 = V$, and label each point with the value of r, s, u, or v to which it corresponds. (The letters y_1 , y_2 , y'_1 , y'_2 are temporary, and should not appear on the diagram.) Then if the line joining two points r and u is parallel to the line joining two points s and r, the four values of r, s, u, v will satisfy the given equation. In this and the following methods, a parallel ruler, or a pair of draftman's triangles, will be useful in reading the chart. A "key"

COT v = cot r cos s + csc r sin s cot uKey: Connect $\binom{(r,s)}{r}$ and u by Parallel Lines

Fig. 27.

will be useful in reading the chart. A "key" stating which points are to be joined with which, should be clearly given on the diagram.

EXAMPLE (Fig. 28). Let $32.2 \text{ } r = us^2$, or $\log r - 2 \log s = \log u - \log (32.2 \text{ } s)$. Here $R = \log r$, $S = 2 \log s$, $U = \log u$, $V = \log (32.2 \text{ } r)$.

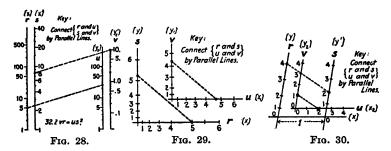

Method B. Given, an equation of the form

$$\frac{R}{S} = \frac{U}{V}$$

Method C. Given, an equation of the form

$$R - S = \frac{V}{U}$$

In Fig. 30, take a pair of axes, x,y, and through the point x = 1 draw a third axis, y', parallel to y. Also, take a second pair of axes, x_2, y_2 , parallel to (or coinciding with) the axes of x and y. Having chosen a suitable unit for x and x_2 , and a suitable unit for y, y', and y_2 , lay off the values of R and

S along y and y', respectively, labeling each point with the value of r or s to which it corresponds; and lay off the values of U and V along x_2 and y_2 , labeling each point with the value of u or v to which it corresponds. Then if the line joining two points r and s is parallel to the line joining two points u and v, the four values r, s, u, v will satisfy the given equation. This form of chart is sometimes called a "Z-chart."

For further examples, see R. C. Strachan, "Nomographic Solutions for Formulas of Various Types," Trans. Am. Soc. Civil Engineers, vol. 78, 1915.

VECTOR ANALYSIS

Many problems involving directed magnitudes can be advantageously treated by the methods of vector analysis. The following is a brief summary of the principal definitions and formulæ.

A set of arrows, each arrow having a given *length* and pointing in a given *direction*, is called a set of **vectors**, provided they combine by addition according to the parallelogram law (see below). Notation: a or \bar{a} for a vector; a or |a| for its length. Two "free" vectors are equal if they have the same length and point in the same direction; two "sliding" vectors are equal if they have the same length and direction, and also lie in the same line.

A scalar is any real number, positive, negative, or zero.

Addition of vectors.—If an arrow **a** is immediately followed, tip to tail, by **a second** arrow **b**, then the arrow which runs from the beginning of **a** to the end of **b** is called the **sum** of **a** and **b**, denoted by **a** + **b**. Conversely, if **a** + **x** = **b**, then **x** = **b** - **a**. The laws of operation for + and - are the same as in ordinary algebra (pp. 112, 124). If m is a scalar, then m**a** means a vector having the same direction as **a**, and m times its length.

Multiplication of vectors is of two kinds, as follows:

The scalar product, or dot product, of two vectors \mathbf{a} and \mathbf{b} , denoted by $\mathbf{a} \cdot \mathbf{b}$ —or sometimes by Sab, or by (ab) in round parentheses—is defined as the scalar quantity $ab \cos \theta$, where θ is the angle between \mathbf{a} and \mathbf{b} .

EXAMPLE. If \mathbf{F} is a force whose point of application moves along a vector distance \mathbf{x} , then $\mathbf{F} \cdot \mathbf{x} = work$ done by \mathbf{F} during this displacement.

Peculiarities of scalar products: (1) Since $a \cdot b$ is not a vector, expressions like $(a \cdot b) \cdot c$ will not occur; (2) from $a \cdot x = a \cdot y$ we cannot infer that x = y, hence, quotients will not occur; (3) from $a \cdot b = 0$, it follows that a is perpendicular to b (unless a or b is zero).

On the other hand, scalar products are like ordinary products in the following respects: $\mathbf{a} \cdot \mathbf{b} = \mathbf{b} \cdot \mathbf{a}$, and $(\mathbf{a} + \mathbf{b}) \cdot (\mathbf{c} + \mathbf{d}) = \mathbf{a} \cdot \mathbf{c} + \mathbf{a} \cdot \mathbf{d} + \mathbf{b} \cdot \mathbf{c} + \mathbf{b} \cdot \mathbf{d}$; also, $m(\mathbf{a} \cdot \mathbf{b}) = (m\mathbf{a} \cdot \mathbf{b}) = \mathbf{a} \cdot (m\mathbf{b})$, where m is any scalar.

The vector product, or cross product, of two vectors \mathbf{a} and \mathbf{b} , denoted by $\mathbf{a} \times \mathbf{b}$ —or sometimes by $\mathbf{V} \mathbf{a} \mathbf{b}$, or by $[\mathbf{a} \mathbf{b}]$ in square brackets—is defined as the vector whose length is ab sin θ , where θ is the angle between \mathbf{a} and \mathbf{b} , and whose direction is perpendicular to the plane of \mathbf{a} and \mathbf{b} (in such a sense that a right-handed screw advancing along $\mathbf{a} \times \mathbf{b}$ would turn \mathbf{a} toward \mathbf{b}).

EXAMPLE. If F is a force acting on a particle whose radius vector is r, then rxF = the torque of F about the origin.

Peculiarities of vector products: (1) $\mathbf{a} \times \mathbf{b} = -\mathbf{b} \times \mathbf{a}$, so that the order of the factors is always important; (2) $\mathbf{a} \times \mathbf{a} = 0$; (3) it is not true that $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \times \mathbf{b}) \times \mathbf{c}$; (4) from $\mathbf{a} \times \mathbf{x} = \mathbf{a} \times \mathbf{y}$ it does not follow that $\mathbf{x} = \mathbf{y}$; hence, quotients will not occur; (5) from $\mathbf{a} \times \mathbf{b} = 0$, it follows that \mathbf{a} and \mathbf{b} are parallel (unless \mathbf{a} or \mathbf{b} is zero).

On the other hand, as in ordinary algebra

$$(\mathbf{a} + \mathbf{b}) \times (\mathbf{c} + \mathbf{d}) = \mathbf{a} \times \mathbf{c} + \mathbf{a} \times \mathbf{d} + \mathbf{b} \times \mathbf{c} + \mathbf{b} \times \mathbf{d},$$

provided the order of factors in each product is preserved; also,

 $m(\mathbf{a} \times \mathbf{b}) = (m\mathbf{a}) \times \mathbf{b} = \mathbf{a} \times (m\mathbf{b})$, where m is any scalar. Further laws are:

$$\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c}) = \mathbf{b} \cdot (\mathbf{c} \times \mathbf{a}) = \mathbf{c} \cdot (\mathbf{a} \times \mathbf{b}); \text{ and } \mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}.$$

Vector Differentiation. If $\mathbf{r} = \mathbf{f}(t)$ gives a vector \mathbf{r} as a function of a scalar t, then $d\mathbf{r}/dt = \lim \{ [\mathbf{f}(t + \Delta t) - \mathbf{f}(t)]/\Delta t \}$ as Δt approaches zero.

$$d(\mathbf{a} + \mathbf{b}) = d\mathbf{a} + d\mathbf{b}, \quad d(m\mathbf{a}) = m(d\mathbf{a}) + (dm)\mathbf{a},$$

$$d(\mathbf{a} \cdot \mathbf{b}) = (d\mathbf{a}) \cdot \mathbf{b} + \mathbf{a} \cdot (d\mathbf{b}), \quad d(\mathbf{a} \times \mathbf{b}) = (d\mathbf{a}) \times \mathbf{b} + \mathbf{a} \times (d\mathbf{b}).$$

EXAMPLE. If $\mathbf{r} = \mathbf{f}(t)$ gives the position-vector of a moving particle as a function of the time t, then $d\mathbf{r}/dt = its$ vector velocity, \mathbf{v} , and $d\mathbf{v}/dt = its$ vector acceleration, a. If \mathbf{m} and \mathbf{n} are unit vectors in the direction of the tangent and normal to the path at the time t, then $\mathbf{v} = v\mathbf{m}$, where v = ds/dt = the (scalar) path-velocity, and $d\mathbf{m} = [(ds/R)]\mathbf{n}$, where R = the (scalar) radius of curvature of the path. Then

$$\mathbf{a} = \frac{d(v\mathbf{m})}{dt} = \frac{dv}{dt}\mathbf{m} + v\frac{d\mathbf{m}}{dt} = \frac{dv}{dt}\mathbf{m} + \frac{v^2}{R}\mathbf{n}.$$

Here dv/dt and v^2/R are the familiar expressions for the components of acceleration along the tangent and normal.
